Colonel **Sinclair** said there was a time when the materials were for the most part inorganic, and could be standardised by tests, but they were getting right away from that now to the use of organic extracts, extracts from various glands in human beings or animals as substitutes for ordinary drugs. Obviously, these required to be subjected to physiological or chemical tests, and it was very important that they should be subjected to those tests by recognised authorities. There was, for example, pituitrin, an extract from a small gland in the brain. This was a very potent substance and was used for a variety of purposes. It was quite possible that practitioners using a particular brand of pituitrin might be quite accustomed to its effects, but in an emergency a man might use a brand which had not been adequately standardised and which might be five or ten times as strong as the brand with which he was familiar. In such a case where the intention was to stimulate a wound sufficiently to secure contraction, the effect of a drug of unknown strength might be to cause a rupture of the wound from over-stimulation. Another illustration was furnished by the valuable substance known as insulin. With the wider use of this drug other manufacturers of it would spring up and their products might be of various standards, and there might be preparations altogether too strong for general use. He cordially supported the measure.

Dr. **Vernon Davies** said the Bill was long overdue. He thought, however, that certain alterations would require to be made so that a serum which might be produced abroad, and had certain special properties, should be allowed to be brought in under licence without all the restrictions imposed by the Bill as it stood. He suggested that as many as possible of the Members of the House who were medical men should be placed on the committee to which the Bill was referred.

Mr. A. V. **Alexander**, on behalf of the Labour Party, supported the Bill.

The Bill was read a second time and committed to a committee of the whole House.

Diseases of Animals Bill.

Mr. E. **Wood** (Minister for Agriculture) moved the second reading of the Diseases of Animals Bill, a measure to provide for contributions to be paid out of moneys provided by Parliament as compensation for the slaughter of cattle in England and in Northern Ireland on the ground of disease.

Dr. **Vernon Davies** asked the Minister with regard to the provision as to the slaughter of cattle in case of the existence or suspected existence of tuberculosis what evidence he required? Was it to apply to tuberculosis of the udder with the consequent production of tuberculous milk, and the danger of communicating tuberculosis of the lungs, or was it to apply to tuberculosis of the lungs, and in that case would reliance be placed simply upon the tuberculin test? He also asked the Minister if he would bear in mind the possibility of vaccine treatment for these cattle, an experiment which he believed was just about to be commenced. If it were successful it would probably effect a great saving to the State.

Sir R. **Luce** said that the tubercle was of two kinds. There was a distinct form of tuberculosis which might be absolutely local and not circulating in the blood at all and in no way affecting the eatable parts of the food. The muscle of the body which formed the largest portion of the food was very rarely infected with tubercle at all. There were, of course, cases in which the udder of the cow which was infected and produced tuberculous milk was practically the only part of the cow that was affected, and this class of cow might be the most important class to destroy as they were the most potent source of tubercle to children. But the rest of the carcass apart from the udder might be absolutely innocuous to the community. It would be a great waste that such animals should be completely destroyed.

Lieut.-Colonel **Fremantle** said he preferred to err on the side of safety, but it seemed to him ridiculous that they should go in for a policy of slaughter in these cases when they were on the brink of discoveries which would absolutely eliminate the necessity of slaughter. If meat was properly butchered and marketed there would not be the same danger of meat being unfit for consumption being exposed as food. If they took greater precautions they could allow a great deal of latitude. Although he believed this Bill was necessary and the compensation to be paid was necessary, he maintained that hand in hand with it the Ministry of Health should go forward with the policy of seeing that butchering was carried out on proper principles and of ensuring better veterinary inspection.

Mr. **Wood** said he was satisfied on such inquiries as he had been able to make from the Minister of Health that

This letter is written in order to call attention to the need of not accepting too readily as actually true a statement from a donor with reference to his blood group. An example may make this clear. At a large London hospital it was decided to transfuse a patient. This patient had been grouped while in that hospital as group II. (using B. W. and Co.'s sera). A donor presented himself as available for this patient and stated that he himself was a group II., since his blood had been so grouped a fortnight previously at another large London hospital. As a precautionary measure the blood of the patient and of the donor were put up against each other, and that of the donor was also grouped by means of stock grouping sera (B. W. and Co.'s). It was then found that the donor's blood was (i.) incompatible with that of the patient, and (ii.) belonged to group III.

Had the donor's statement been accepted and the transfusion performed, a fatal result might have occurred. Such an incident suggests that the blood of patient and prospective donor should always be tested against each other. Further, the eye alone should not be depended on for detecting the presence of agglutination, but a strong lens or a microscope should be used, more especially if stock serum is used for grouping. A fatal result has occurred when the eye alone was depended on.

I am, Sir, yours faithfully,
E. L. HUNT,
Bacteriologist, St. George's Hospital, S.W. 1.

July 18th, 1925.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 15TH.

Custard and Egg Powders.

Mr. **WALTER BAKER** asked the Minister of Health whether he had received a copy of the report on custard and egg powders which had been presented to the Monmouthshire County Council by the President of the National Analysts' Association; and whether, in view of the fact that these powders were in the main dyed starch and that six eggs to the ton was sufficient to comply with the law, he proposed to take any action.—Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied: Yes, Sir, my right hon. friend has received a copy of the report. He has no power to lay down any rules as to the composition of custard and egg powders so long as they are not injurious to health.

Sanitary Inspection of Offices.

Colonel **DAY** asked the Home Secretary if he was aware that divers Metropolitan borough councils had made representations suggesting that the sanitary officers should be empowered to inspect offices where wage-earners were employed in the same way as factories and workshops; and would he consider introducing legislation with a view to the protection which was afforded workers in factories and workshops being extended to office workers.—Mr. **G. LOCKER-LAMPSON** (Under Secretary for Home Affairs) replied: No such representations have been made to the Home Office, but I understand that representations to this effect have been received by the Ministry of Health from two of the Metropolitan borough councils. My right hon. friend is afraid he cannot promise any legislation in the direction suggested.

THURSDAY, JULY 16TH.

Publication of Trevethin Committee Evidence.

Mr. **SNELL** asked the Minister of Health whether Colonel Harrison, a permanent official of the Ministry of Health, was acting under instructions when, at the recent congress of the Royal Institute of Public Health, held at Brighton, he prevented Mr. Wansey Bayly, the hon. secretary of the Society for the Prevention of Venereal Diseases, from quoting evidence which was given before the Trevethin Committee, on the ground that such evidence was confidential; whether this evidence was in fact confidential; and would he undertake that permanent officials of his department, except when acting under his instructions, would not prevent valuable information on important health subjects from being given to the public by competent medical men.—Mr. **NEVILLE CHAMBERLAIN** replied: No instructions in this matter were given to the officer referred to. As regards the second part of the question, I am informed that no pledge was given to witnesses before the Trevethin Committee that their evidence would be regarded as confidential and not published, but the evidence has not been published and was not available to members of the congress, and its chairman ruled that quotations from such evidence would be out of order. I am unable to accept the implication conveyed in the last part of the question.

Uninsured Persons.

Mr. **HERBERT WILLIAMS** asked the Minister of Health the number of employed persons in this country not insured under the National Health Insurance Acts.—Mr. **NEVILLE CHAMBERLAIN** replied: No precise information of the kind desired by my hon. friend is available. The number of employed persons aged 12 or over in Great Britain in 1921, according to the census of that year, was 17,403,053, of whom it is estimated that 16,432,000 were over 16, and the estimated number of persons entitled to benefits under the National Health Insurance Acts in the same year was 15,134,000. The latter figure, however, includes some persons who had ceased to be employed, and for this and other reasons it is not directly comparable with the census figure. The balance of 1,298,000, therefore, is only a rough approximation to the number of uninsured employed persons, of whom the principal groups are non-manual workers earning more than £250 a year and persons engaged in excepted employment under the Crown and local authorities and certain statutory companies.

Health Visitor's Salary.

Mr. **GERALD HURST** asked the Minister of Health whether he was aware that the Dorset County Council was advertising for a health visitor at a salary of £148 a year, out of which the person appointed had to contribute £7 15*s.* a year towards the superannuation funds and to find her own bicycle; and whether, seeing that this salary, with its yearly increments, was far below the normal scale, he would draw this council's attention to the effect of its action upon the standard of trained nurses likely to be attracted into the public health service.—Mr. **NEVILLE CHAMBERLAIN** replied: Yes, Sir, I am in communication with the county council on the subject.

Optical Treatment for Panel Patients.

Mr. **BLUNDELL** asked the Minister of Health the difference between optical treatment, which was previously allowed to be given as an additional benefit under the Health Insurance Acts, and ophthalmic treatment, as now allowed.—Mr. **NEVILLE CHAMBERLAIN** replied: The difference is that with the new definition of the benefit it has been possible to make arrangements whereby an insured person is in a position to obtain the advice of an ophthalmic specialist when it is required in the opinion of his medical practitioner. Under the previous definition it was a matter of doubt how far this could be done.

Scarlet Fever from Ice-Cream.

Colonel **DAY** asked the Minister of Health if he was aware of the recent outbreak of scarlet fever in Portsmouth which was traceable to ice-cream made by one manufacturer in whose employ a boy assistant was found to be suffering from the disease; would he, in the interests of public health, make an order that early notice of any illness of the principals or employees of an ice-cream manufactory should be made immediately to the local medical officer of health, and that such notice should become obligatory; and would he consider the advisability of powers being vested in medical officers of health so as to allow the inspection of places where ice-cream was made, and inspection of persons occupied with the manufacture or distribution of ice-cream.—Mr. **NEVILLE CHAMBERLAIN** replied: I have received a copy of the report of the medical officer of health on the outbreak referred to. Provision is already included in the Infectious Disease (Notification) Act and in regulations made by my department for the notification of all cases of any of the principal infectious diseases, and a special provision is included in a Portsmouth local Act requiring manufacturers of and dealers in ice-cream to give notice of the outbreak of any such disease amongst their employees. I doubt whether it would be practicable to enforce a regulation that all cases of illness, however slight, should be notified. With regard to the regulation of places where ice-cream and other food is prepared, many local authorities in addition to the town council of Portsmouth have obtained special local Act powers as to ice-cream.

FRIDAY, JULY 17TH.

The Summer-Time Bill.

The Summer-Time Bill was considered on report.

On Clause 1 (which makes Summer Time permanent and extends the period prescribed in the previous Acts),

Sir **H. CAUTLEY** moved an amendment to leave out Subsection (2), the effect of which was to limit the period of Summer Time to that fixed by the existing law—i.e., from 2 o'clock on the Sunday morning following the third Saturday in April to 2 o'clock on the Sunday morning following the third Saturday in September. He said that there was no objection to the proposal to make summer time perpetual; the only point of controversy was as regarded the date on which Summer Time should begin and end. The promoters of the Bill proposed to add about a fortnight at the beginning of the period, and a fortnight or three weeks at the end, making Summer Time finish on the first Saturday in October. Although a very good case could be made that no sufficient time had elapsed since the compromise of 1922, he felt that this was a matter which should, if possible, be amicably settled. The promoter of the Bill had made an offer which he thought generous, though he (Sir H. Cautley) could not accept it as such. This offer was to give up the early part of the period leaving the commencing date as at present, provided the opponents of the Bill would agree to the full period proposed by the Bill at the end—namely, the first Saturday in October. As chairman of the Conservative Agriculture Committee, he wished to say that they would accept that compromise if the House was willing to accept it. (Hon. Members: "No.")

Dr. Graham Little said he wished to voice more especially the considered opinion of the medical profession inside and outside the House. Arguments in favour of the Bill seemed so overwhelming and objections so trivial that it was hard to understand why there should be any difficulty about it. This was a measure of far-reaching importance to the health and happiness of the community. It was really one of the most important Bills that had ever been before the House or the country. He would point out the profound significance of medical unanimity on this Bill. The British Medical Association in 1923 passed this resolution: "That the British Medical Association regrets that Summer Time has been curtailed this year, as it is our opinion that Summer Time is beneficial to the health of the nation." In 1921 the Society of Medical Officers of Health passed this resolution: "The Society regards the institution of Summer Time as a great benefit to the community as a whole and can find no sufficient evidence to support the view that it must prove detrimental to the health of infants and young persons." That resolution was confirmed in 1923 and 1924. In connexion with a deputation to the Home Secretary the medical officers of health brought to his notice the resolution. He (Dr. Little) had been connected with the staff of a London hospital for children, and he said without hesitation that the statements made about the difficulty of getting children to sleep was unmitigated "tosh." He urged very strongly that there should be no curtailment of the period of Summer Time.

After further discussion, the closure was moved by the promoter of the Bill (Lieut.-Colonel Lambert Ward), and on a division Sir H. Cautley's amendment was rejected by 201 votes to 68.

An amendment in the name of Sir R. Sanders, providing that Summer Time should begin on the third Saturday in April instead of the first Saturday as proposed in the Bill, was then agreed to without a division.

Sir H. Hope moved a further amendment to fix the last Saturday in September instead of the first Saturday in October as the date of the termination of Summer Time, which after some discussion was defeated by 228 votes to 56. The Bill was then read a third time without a division.

Therapeutic Substances Bill.

Mr. Neville Chamberlain (Minister of Health), in moving the second reading of the Therapeutic Substances Bill (which has already passed through the House of Lords), said he believed that it would have the assent of all parties inasmuch as it was no exaggeration to say that the lives of many people would benefit from its early passage into law. It dealt with the standardisation of vaccines, sera, toxins, antitoxins, antigens, and insulin. Practically all civilised countries had an official standardisation for these various substances and as to their purity and potency—France, Germany, Italy, Spain, the United States, Norway, Sweden. Preparations which had failed to pass the test of foreign countries were liable to be imported here. It was proposed that no one should be allowed to manufacture these substances without a licence. A joint committee would be set up consisting of the Minister of Health, the Secretary for Scotland, and the Home Secretary for Northern Ireland, with power to make regulations, to prescribe standards and tests, and from time to time to make conditions. Veterinary substances were excluded except in so far as might be necessary in certain cases.

Major-General Sir R. Luce said in carrying this matter one stage further they had behind them medical and scientific opinion. The substances dealt with were medically roughly of three kinds. First there were those extremely difficult chemical compounds, such as salvarsan. The regulations under the Bill would help to make quite certain that these substances did not get into the hands of people who were not qualified to deal with them. He hoped that in committee it would be possible to add to the Advisory Committee a representative of the body of general practitioners who were directly responsible for the use of these substances, possibly nominated by the British Medical Association.

Colonel Sinclair said there was a time when the materials were for the most part inorganic, and could be standardised by tests, but they were getting right away from that now to the use of organic extracts, extracts from various glands in human beings or animals as substitutes for ordinary drugs. Obviously, these required to be subjected to physiological or chemical tests, and it was very important that they should be subjected to those tests by recognised authorities. There was, for example, pituitrin, an extract from a small gland in the brain. This was a very potent substance and was used for a variety of purposes. It was quite possible that practitioners using a particular brand of pituitrin might be quite accustomed to its effects, but in an emergency a man might use a brand which had not been adequately standardised and which might be five or ten times as strong as the brand with which he was familiar. In such a case where the intention was to stimulate a wound sufficiently to secure contraction, the effect of a drug of unknown strength might be to cause a rupture of the wound from over-stimulation. Another illustration was furnished by the valuable substance known as insulin. With the wider use of this drug other manufacturers of it would spring up and their products might be of various standards, and there might be preparations altogether too strong for general use. He cordially supported the measure.

Dr. Vernon Davies said the Bill was long overdue. He thought, however, that certain alterations would require to be made so that a serum which might be produced abroad, and had certain special properties, should be allowed to be brought in under licence without all the restrictions imposed by the Bill as it stood. He suggested that as many as possible of the Members of the House who were medical men should be placed on the committee to which the Bill was referred.

Mr. A. V. Alexander, on behalf of the Labour Party, supported the Bill.

The Bill was read a second time and committed to a committee of the whole House.

Diseases of Animals Bill.

Mr. E. Wood (Minister for Agriculture) moved the second reading of the Diseases of Animals Bill, a measure to provide for contributions to be paid out of moneys provided by Parliament as compensation for the slaughter of cattle in England and in Northern Ireland on the ground of disease.

Dr. Vernon Davies asked the Minister with regard to the provision as to the slaughter of cattle in case of the existence or suspected existence of tuberculosis what evidence he required? Was it to apply to tuberculosis of the udder with the consequent production of tuberculous milk, and the danger of communicating tuberculosis of the lungs, or was it to apply to tuberculosis of the lungs, and in that case would reliance be placed simply upon the tuberculin test? He also asked the Minister if he would bear in mind the possibility of vaccine treatment for these cattle, an experiment which he believed was just about to be commenced. If it were successful it would probably effect a great saving to the State.

Sir R. Luce said that the tubercle was of two kinds. There was a distinct form of tuberculosis which might be absolutely local and not circulating in the blood at all and in no way affecting the eatable parts of the food. The muscle of the body which formed the largest portion of the food was very rarely infected with tubercle at all. There were, of course, cases in which the udder of the cow which was infected and produced tuberculous milk was practically the only part of the cow that was affected, and this class of cow might be the most important class to destroy as they were the most potent source of tubercle to children. But the rest of the carcass apart from the udder might be absolutely innocuous to the community. It would be a great waste that such animals should be completely destroyed.

Lieut.-Colonel Fremantle said he preferred to err on the side of safety, but it seemed to him ridiculous that they should go in for a policy of slaughter in these cases when they were on the brink of discoveries which would absolutely eliminate the necessity of slaughter. If meat was properly butchered and marketed there would not be the same danger of meat being unfit for consumption being exposed as food. If they took greater precautions they could allow a great deal of latitude. Although he believed this Bill was necessary and the compensation to be paid was necessary, he maintained that hand in hand with it the Ministry of Health should go forward with the policy of seeing that butchering was carried out on proper principles and of ensuring better veterinary inspection.

Mr. Wood said he was satisfied on such inquiries as he had been able to make from the Minister of Health that if the local authorities did their duty, as he had every reason to think they did, there was no meat passing into human consumption that was or might be prejudicial to human health. But if any case could be established that there was a chance of unsound meat being sold, he would be very willing in conjunction with the Minister of Health to take effective means to stop it.

The Bill was read a second time and committed to a committee of the whole House.

Monday, July 20th.

Civil Service Pensions in India.

Sir **Charles Oman** asked the Under Secretary of State for India whether European British subjects serving in the provincial services in India were entitled to retire on a proportionate pension, similar to that recommended by the Lee Report for the superior civil services; and, if not, whether any measures were contemplated for assimilating their position to that of the other civil services in this respect.—Earl **Winterton** replied: Eligibility under the Premature Retirement Rules is limited to members of the All India Services. No general extension of the right to retire under these rules is contemplated, but the Government of India is examining in consultation with local governments the possibility of entertaining applications from individual officers whose circumstances may appear to be of a very exceptional nature.

Burdens of the Milk and Dairies Act.

Mr. **Everard** asked the Minister of Health whether, in view of the burdens which the Milk and Dairies (Consolidation) Act, 1915, was likely to place on the owners and occupiers of agricultural holdings, he would consider the further postponement of the operation of this Act.—Sir **Kingsley Wood** replied: I think my hon. friend is unduly apprehensive as to the probable effect of the Act on the owners and occupiers of agricultural holdings, and in view of its importance as a public health measure my right hon. friend cannot contemplate the introduction of legislation to provide for its further postponement.

Valuation of Approved Societies.

Mr. **Thomas Williams** asked the Minister of Health whether the valuation of all approved societies under the National Health Insurance Act had taken place up to one period; if not, would increased benefits of societies whose valuation was delayed be made retrospective to July, 1925; and the reason why all valuations were not made at the same period and additional benefits made available at the same time for all members.—Sir **Kingsley Wood** replied: For the purposes of the second valuation approved societies and branches were divided into two groups, to be valued respectively as at Dec. 31st, 1922, and Dec. 31st, 1923. For those which have been valued as at the former date the schemes of additional benefits following this valuation operate from July 6th, 1925, and for the other group the scheme will commence in July, 1926. These arrangements were agreed to by the Consultative Council representing approved societies of all types, and were found to be necessary in order to avoid either a considerable increase in the number of the valuers and their staff or alternatively a prolongation of the period elapsing between the date of valuation and the commencement of the additional benefits provided as the result of the valuation.

Coroners' Inquiries in Murder Cases.

Mr. **Dixey** asked the Home Secretary whether he proposed to introduce legislation to remedy defects in coroners' inquiries in murder cases at an early date.—Sir W. **Joynson-Hicks** replied: Yes, Sir.

Further Accommodation for London University.

Dr. **Little** asked the Secretary to the Treasury whether the Senate of the University of London had declined the offer of April, 1920, made by the then President of the Board of Education, of the Bloomsbury site; and whether the Treasury was prepared to entertain alternative proposals for increasing the present accommodation at South Kensington for the central offices of the University.—Mr. W. **Guinness** replied: The answer to the first part of the question is in the affirmative. In reply to the second part the Treasury have already informed the Senate of their willingness to consider any practicable alternative proposal for an increase, without undue cost, of the accommodation for the central offices of the University which the Senate feel able to suggest.

Export of Morphia to China.

Mr. **Scrymgeour** asked the Secretary to the Treasury whether he was aware that packets of morphia, bearing the labels of three different London firms—namely, J. A. Wink and Company, manufacturing chemists, Battersea, P. Nicolaidi, and T. and H. Smith, Limited, 25, Christopher-street—were being exported for the purpose of being smuggled into China; and what steps were being taken in the matter. —Sir W. **Joynson-Hicks** replied: The answer is in the negative. The two first-named firms are not licensed to manufacture or deal in morphine and no licences for the export of morphine are granted them. In the case of the last-named firm, who are manufacturers of morphine, export licences would only be granted if my department is satisfied that the drug is required for medical or scientific purposes, but I think it is only right to say, in view of the fact that the firm's name is mentioned in the question, that I am not aware of any evidence to suggest that they have taken part in or connived at attempts to smuggle the drug into China or elsewhere. The hon. Member is probably aware that it is a common trick of the illicit dealers to put forged labels bearing the names of well-known firms on their wares.

Telephones and Rural Medical Service.

The House went into Committee of Supply on a vote of £32,958,000 for the salaries and expenses of the Post Office, including telegraphs and telephones, Captain **Fitzroy** (Deputy Chairman of Committees) in the chair.

Mr. **Macpherson** said he was speaking for the whole of the Highlands where there were houses and small communities 20, 30, or 40 miles from the nearest doctor, and there was no possibility of any person who might be taken suddenly ill getting a doctor, or near one, without a telephone. The telegraph offices were closed at night and he knew of case after case of extreme hardship because of the lack of extension of the rural telephone system. He was sure the House would agree to any loss that might be caused by the extension of this system.

Sir R. **Hamilton**, the Member for Orkney and Shetland, said that, as the Postmaster-General was aware, a petition had recently been sent to him from the island of Papa Westray which furnished a very good example of the difficulties which people suffered who lived in islands where there was no telephonic communication either with the mainland or the next largest island. Papa Westray was separated from the next largest island by a sound through which ran a strong current and it was dangerous for an open boat to cross at night in the winter. No doctor lived on the island, which had over 150 inhabitants, and it would be of inestimable advantage to them to be able to communicate by telephone with the doctor, not necessarily that the doctor should come across, but in order that he might have a statement of the case which would enable him to send over the telephone instructions as to how the patient should be treated.

Major **Price** said that in a village in North Pembrokeshire the other day two accidents happened within an hour or two. The nearest doctor was eight miles away. The telephone wire was down, as it had been very often. The only means of communication was by way of pony and trap. The patient had to be sent to the county hospital, which was 15 miles away, and there was a lapse of 11 or 12 hours before he could be got there, all of which might have been avoided if the telephone had been available. He urged the Postmaster-General to develop the telephone system so that it might be useful to the whole community, and specially to the rural community.

Mr. **Buchanan** urged the necessity for telephone kiosks, conveniently situated near the homes of the people so that they could use them, say, in connexion with a maternity case.

Lieut.-Colonel **Heneage** joined in the plea for increased telephone facilities and said in many villages at the present time the only way of summoning a doctor was by sending a man on a bicycle for him, with the result that sometimes the doctor was hours late in arriving.

Sir W. **Mitchell-Thomson** (Postmaster-General) said he appreciated as much as any hon. Member the importance of developing rural telephones. New rural exchanges were being opened at the rate of something like 20 per month. But he asked hon. Members not to press him too hard, as he had to consider the question of finance. Until the science of wireless telephony as opposed to wireless telegraphy had developed further he did not think it was practicable to instal wireless communication between the islands. So long as they were confined to wireless telegraphy the cost was out of the question.

Tuesday, July 21st.

Medical Treatment of Tuberculous Men.

Mr. **Gillett** asked the Minister of Pensions if instructions had been sent to tuberculosis officers to intimate to their ex-service patients who had been under treatment for periods of from three to six years to get light work; and whether, seeing that some patients who had been so informed were advanced cases of tuberculosis and that with so many unemployed it was impossible for such ex-Service men to secure the light work ordered, he would withdraw these instructions.—Lieut.-Colonel G. F. **Stanley** (Parliamentary Secretary to the Ministry of Pensions) replied: It would not be competent for the Ministry of Pensions to issue instructions to tuberculosis officers regarding the medical treatment of cases under their care, and no such instructions have been issued.

Sanatorium Treatment for Pensioners.

MR. LAWSON asked the Minister of Pensions if he would say what was the number of pensioners in receipt of pension at 100 per cent. following a course of sanatorium treatment; and whether he would consider the desirability of granting the special rate of 100 per cent. to all men discharged from sanatoria irrespective of its being a first, second, or third course of sanatorium treatment.—Lieut.-Colonel G. F. STANLEY replied: About 10,000 men are in receipt of pension at the rate of 100 per cent. in respect of total disablement due to pulmonary tuberculosis; but I regret that I am unable to say how many of these fall under the special arrangement for men who have completed a course of sanatorium treatment. With regard to the second part of the question, my right hon. friend is in agreement with the reply given by his predecessor to a similar question on July 31st, 1921.

Medical News.

THE CONTRIBUTION OF OPTICAL INSTRUMENT MAKERS TO MEDICAL SCIENCE.—In his presidential address, delivered on July 23rd at a luncheon of the British Optical Instrument Manufacturers Association, Mr. F. Twyman, F.R.S., welcomed the most representative gathering of the optical instrument industry which has ever taken place. He dealt in succession with the contributions of this industry to various important sections of national life. Speaking of developments in the microscope, Mr. Twyman said that the series of apochromatic objectives now provided in this country are superior to any made abroad, adding that many who are doing exacting microscopic work are discarding foreign lenses for British. The important British work on filter-passing micro-organisms demanded, he said, accuracy of focusing and rigidity which was not provided by any existing stand, and such a stand had now been evolved in this country. Improvements in illuminating systems were, if anything, more important than those in objectives. The evolution of the dark-ground illuminator, permitting of the use of higher powers, had resulted almost immediately in the acquisition of new knowledge of disease. He mentioned the combined illuminator used in Mr. J. E. Barnard's work in which a high aperture dark-ground illuminator is mounted concentrically with an encircling quartz condenser. While the former secured visibility and was used to locate the micro-organisms, the latter transmitted ultra-violet light and secured an image on the photographic plate. Mr. Twyman pointed out how essential to medical research is an efficient optical industry. British investigators knew the limitations of their apparatus and just what their requirements were. They laid their knowledge and requirements before the instrument-maker and in a short time were supplied with the instruments that enabled them to go forward and obtain results. Most of the instrumental essentials for the recent work of Dr. Gye and Mr. Barnard were, he was glad to say, British, like the work itself.

BEIT FELLOWSHIPS.—At a recent meeting of the trustees of the Beit Memorial Fellowships for Medical Research the appointment of Mr. Edward Wood, M.P., as a trustee was recorded on the minutes. The annual report, read by the hon. secretary, Sir James K. Fowler, notes the appointment of Dr. David Keilin, the first senior fellow to be University Lecturer on Parasitology at Cambridge. Dr. V. D. Allison, while holding a junior fellowship, was appointed Lecturer on Bacteriology at Queen's University, Belfast; Dr. Robert Keith Cannan and Dr. Ethel M. Luce, at the termination of their junior fellowships, were elected to Rockefeller Medical Fellowships tenable in the United States; Mr. Frank Cook, a junior fellow, has been appointed assistant obstetric surgeon to Guy's Hospital; and Dr. John Maurice Campbell, a junior fellow, has been awarded the Radcliffe prize at Oxford. There is still urgent need, the report states, for additional lectureships, assistant professorships, and professorships, so that a future may be in prospect for those who have gone far to commit themselves to a life to be spent in teaching and research.

The following are the names of candidates elected to fellowships, together with an indication of their proposed research:—

Senior Fellowship.—Herbert Davenport Kay.

Fourth Year Fellowships.—Ernest Basil Verney and John Lewis Rosedale.

Junior Fellowships.—George Hardy Eagles, M.D. Toronto. The specific agglutinogenic properties of streptococcus scarlatinæ and the possible further specific grouping of hæmolytic streptococci occurring in other pathological processes.

Dorothy Mary Needham. (1) A study of the oxidation-reduction potential of various organisms and tissues—e.g., (a) leucocytes in health and disease; (b) comparison of cancer, normal, and embryonic tissue; (c) cells under the influence of ultra-violet light and sunlight—using the method of micro-injection of oxidation-reduction potential indicators. (2) A continuation of the study of the pancreatic factor inhibitory to lactic acid formation in muscle, the nature of its effect upon carbohydrate metabolism, and its relation to insulin.

Ernest Noble Chamberlain, M.B., Ch.B. (Hons.) Liverp., M.D. Liverp., M.R.C.P. Lond. (1) Effects of the anterior lobe of the pituitary gland on the liver and other organs of the body; (2) investigation of the relation of pituitary and other ductless glands to cholesterol metabolism, including the variations found in the various pathological syndromes of endocrine disorders; (3) studies in the inter-relations of the various ductless glands by experimental production of over-dosage with one member of the series.

Eric Newmarch Allott, M.B., B.Ch. Oxf. The Growth of Bacteria on Artificial Media. To attempt to grow bacteria on purely artificial media, consisting of simple compounds, such as simple sugars, amino-acids, and salts, with a view to studying (a) what compounds or types of compound are indispensable for bacterial growth; (b) the variations in the characters of the bacteria according to the medium in which they are grown.

Francis Charles Kelly, B.Sc. Aberd. To continue research on iodine metabolism, especially the iodine requirements of animals and the influence on nutrition of diets deficient in iodine: (1) Feeding experiments on small animals with varying amounts of iodine added to the diet; (2) estimation of the iodine content of thyroid glands of animals fed on different diets; (3) determination by balance experiments of the influence of iodine on mineral metabolism, and especially the protein metabolism.

Derek Ernest Denny-Brown, B.M., B.Ch. New Zealand. To investigate spastic paralyses, decerebrate rigidity, and allied conditions, more particularly with regard to the influence of the sympathetic nervous system upon them.

Benjamin Stanley Platt, M.Sc. Leeds. The Relationship Existing Between the Formation of Peroxides by Bacteria and Certain of the Phenomena of Immunity. (a) An attempt to determine whether some constituents of bacteriological media promote peroxide formation by bacteria more than others, and, if such exist, whether they have any influence on the course of pneumococcal infections in animals; (b) a study of the interactions between bacterial peroxides and leucocytic oxidases as they affect the life of bacteria.

ROYAL SOCIETY OF MEDICINE.—The annual report of Council presented to the general meeting of Fellows on July 1st shows a membership of over 4000, being 400 more than in the first year of war. Over 3000 books have been added each year to the library, which was frequented in the last 12 months by 20,000 readers. In 1914 9000 books were borrowed, and last year 13,000. At the annual meeting the treasurers reported the finances to be in a strong position. A committee is at present engaged in studying further developments in the printing and publishing of the Proceedings.

THE House of the Royal Society of Medicine will be closed during the whole of August for cleaning and repairs.

ACCUMULATED FUNDS OF APPROVED SOCIETIES: DEPUTATION TO THE MINISTER OF HEALTH.—Mr. Neville Chamberlain received on July 20th a deputation representing, amongst others, the following bodies: Hearts of Oak Benefit Society, National Association of Employees' Approved Society, National Conference of Friendly Societies, National Conference of Industrial Assurance Approved Societies, National Deposit Friendly Society, National Union of Railwaymen Approved Society, Rural Workers Approved Society.

Mr. Meller, M.P., Mr. Oakley, M.P., and Mr. Blundell, M.P., and Sir Thomas Neill, who spoke for the approved societies, said that suggestions had been made in the press and in Parliament that part of the burden imposed on industry by the Contributory Pensions Bill could and should be removed either by taking money from the accumulated funds of approved societies or by lowering the contributions. The argument was that the size of the funds that had accumulated indicated that the difference between the income and expenditure was far larger than was required by the needs of the case, and that the insured person would readily agree to any reduction in the benefits that he might receive in exchange for a lessening of the contribution which he, in common with his employer, must pay. Their answer to this argument was that the funds that had accumulated were held in trust for the insured person, by whom, or on whose behalf, they had been paid, and that the possibility of paying additional benefits which had been provided for in the original Act and on the basis of which a number of societies had been formed for those occupations in which sickness incidence was small was a fundamental part of the scheme. They were anxious to receive an assurance from the Minister that he had not been shaken by the widespread attempt that was being made to tamper with the funds of approved societies.

The Minister, in reply, promised to deal with this matter on the third reading. Until what they described as "the attack" had been developed, he could not predict to them what line he would have to take in meeting it, but he could inform them that he was well aware of certain fundamental considerations, such as that the fund from which it was proposed to draw money for the relief of industry was not an aggregate fund, but merely the sum of a number of separate funds belonging to different approved societies. Nor, on the other hand, had those who were suggesting either of these methods of relief indicated what the starting-point was to be—whether the additional benefits given as a result of the first valuation or as a result of the second valuation were to be treated as inviolable. The only assurance that in the nature of things it was possible for him to give them at the present moment was that he would be a party to nothing which would endanger the solvency of societies or involve breach of pledges given by successive Governments.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—At the thirty-eighth meeting of the Commission, besides those already mentioned, evidence was given by the Joint Tuberculosis Council, represented by Sir Henry Gauvain and Dr. G. Lissant Cox, on the need for amendment in the treatment and cash benefits of insured persons suffering from tuberculosis. Mr. Walter Farris was examined on his scheme for fundamental alterations in the financial structure of the scheme.—The thirty-ninth meeting of the Commission was held at the Home Office, Whitehall, on July 14th, Prof. Alexander Gray in the chair. Evidence dealing with the constitution of the Central Fund, the methods of audit of approved society accounts, the accumulation of cash benefits in respect of persons in institutions, and the provision of dental benefit was submitted by Mr. William McLean on behalf of the Grand United Order of Oddfellows Friendly Society. The United Patriots National Benefit Society, represented by Mr. J. M. Roberts, gave evidence recommending the provision of curative treatment at the British spas as a benefit for members of approved societies suffering from rheumatic diseases, this evidence being supported by Dr. Fortescue Fox, past President of the International Society of Medical Hydrology, and Mr. John Hatton, secretary of the British Spas Federation. Thereafter Miss M. A. Hilbery gave evidence as to delays and irregularities in payments of cash benefits.—The fortieth meeting of the Commission was held at the same place on July 16th, Lord Lawrence of Kingsgate in the chair. Evidence was given by Mr. H. Lesser, on behalf of the London Insurance Committee, as to the powers and duties of the Committee and methods of improving the medical benefit service. Mrs. Hubback, representing the National Union of Societies for Equal Citizenship, put forward proposals for improving the position of women under the Act. The Standing Joint Committee of Industrial Women's Organisations, represented by Dr. Marion Phillips, submitted recommendations for extending medical benefit to dependants and widening its scope, for increasing the cash benefits, and for pooling the surpluses of approved societies. Thereafter Mr. W. A. Middleton, acting chief auditor of the National Insurance Audit Department, described the detailed arrangements for audit of the accounts of approved societies and insurance committees.

CANADIAN MEDICAL ASSOCIATION: ANNUAL MEETING AT REGINA.—Delegates from the British, American, and Chinese medical associations were present at the fifty-sixth annual meeting of the Canadian Medical Association held in Regina, Saskatchewan, under the presidency of Dr. David Low (Regina) in the first week of July. A grant of $30,000 (£6000) offered by the Sun Life Assurance Company of Canada to carry on post-graduate extension lecture courses throughout the Dominion was accepted by the Association. The organisation will be directed mainly towards helping the medical man in rural areas to keep abreast of medical advance of medicine. The report on medical education submitted by Dr. D. J. McLean (Winnipeg) emphasised the need for turning out practitioners qualified to render public service, rather than purely scientific men. Dr. T. C. Routley (Toronto), secretary of the Association, announced the opening of negotiations with the Royal College of Surgeons of England for the admission of Canadian medical graduates to membership of the College on easier terms. Dr. M. M. Seymour (deputy Minister of Health for Saskatchewan) foretold the time when communicable diseases would cease to menace mankind. Dr. Forest Leader (Victoria, B.C.) was chosen as president-elect for 1926–27, Dr. A. Primrose (Toronto) as chairman of Council, and Dr. A. T. Bazin (Montreal) as treasurer. Dr. Routley continues to hold office as general secretary. The executive committee is constituted as follows: Dr. David Low, Dr. Forest Leader, Dr. A. T. Bazin, Dr. T. C. Routley, Dr. W. G. Reilly (Montreal), Dr. G. S. Cameron (Peterboro, Ont.), Dr. T. Glenn Hamilton (Winnipeg), Dr. C. F. Martin (Montreal), Dr. J. G. Fitzgerald (Toronto), Dr. G. S. Young (Toronto), Dr. J. S. McEachern (Calgary). Dr. G. S. Seymour (Regina), Dr. F. N. G. Starr (Toronto), and Dr. S. L. Walker (Halifax). Dr. A. D. Blackader (Montreal) was reappointed editor of the *Canadian Medical Association Journal*, with Dr. Bazin as managing editor. Dr. W. H. McGuffin (Calgary) was chosen as president of the Canadian Radiology Society, and Dr. G. C. Brooks (Montreal) continues to act as secretary-treasurer. Victoria, British Columbia, will be the place of meeting in 1926, and the Canadian Radiology Society will meet at the same time and place.

THE King has appointed Sir Thomas J. Horder, Bart., a Knight Commander of the Royal Victorian Order.

CLIMATOLOGICAL CONGRESS AT DAVOS.—The Congress organised by the Davos Institute for Alpine Physiology and Tuberculosis Research will be held, as already announced, from August 16th to 22nd. The programme includes nearly 50 papers and demonstrations distributed among four sections: General, physical-meteorological, biological, and clinical. Dr. Carrière, head of the Swiss Public Health Department, will open the Congress with an address on the Relationship between the Various Climates of Switzerland and the Health of the Population. In the same section Dr. R. King Brown (London) will speak on the Climate of a Big City, and other speakers will include Prof. Dietrich (Berlin), Prof. Hellpach (Karlsruhe), Prof. Levi (Rome). and Dr. Wehrli (Zurich). In the clinical section Dr. Leonard Hill and Sir Henry Gauvain are announced to speak. Membership cards at a cost of 20 (Swiss) francs may be obtained on application at the Davos Research Institute, members being entitled to reduced railway fares and special terms for hotel accommodation.

AMSTERDAM INDUSTRIAL CONGRESS.—The Fourth International Medical Congress of Industrial Accidents and Diseases will take place in Amsterdam from Sept. 5th to 12th next, opening at 3 P.M. on Saturday, Sept. 5th, when the national exhibition will be inaugurated. On Monday, at 2.30 P.M., the ceremonial opening of the Congress takes place, followed by a banquet to the official representatives. At the plenary session on Tuesday morning, Prof. B. Cuneo (France), Dr. L. Teleky (Germany), Prof. J. Glaister (England), Dr. L. Heijermans (Holland), and Dr. F. Zollinger (Switzerland) will take part. Afterwards the Congress breaks up into collateral sections of industrial accident and industrial disease, in each of which papers will be read covering a wide range of subjects. At the plenary session to be held at The Hague on Saturday, Sept. 12th, Dr. Allers (Austria), Sir Thomas Oliver (England), Prof. L. Devoto (Italy), and Dr. A. Oller (Spain) will take part. The programme and further information may be obtained in this country from Dr. H. Menko, hon. sec. to the British Executive Committee, at 2, Grosvenor-gardens, London, N.W. 2.

THE LATE DR. G. S. SIMS.—George Samuel Sims, who died recently at Derby at the age of 70, qualified in 1884 with the L.S.A., having been educated at Owens College, Manchester, and at St. Thomas's Hospital, London. Four years later he obtained the M.R.C.S. and L.R.C.P. Lond. and graduated M.D. Durh. in 1900. For more than 30 years he was district medical officer to the Derby Board of Guardians and for nearly as many medical officer to the Liversage Charity. He was at one time President of the Derby Medical Society. At the outbreak of war, in spite of his age, he volunteered for service with the R.A.M.C., and did valuable work both at home and abroad. His surviving sons, Dr. G. H. Sims and Dr. T. H. Sims, both follow their father's profession.

FACULTY OF MEDICINE, VIENNA.—The Dean of Vienna University announces the following forthcoming courses: (1) Eighteenth International Advanced Course for Practitioners, Sept. 14th to 26th inclusive, covering the most important medical problems of to-day. (2) Practical Training Course for Students, Sept. 25th to Oct. 2nd inclusive. Applicants should send names, titles, and addresses in writing to Dr. A. Kronfeld, Sekretär der Internationalen Fortbildungskursus, Wien IX., Porzellangasse 22. (3) International Advanced Course in Dermatology and Syphilis, Nov. 23rd to Dec. 6th. Apply Dr. Kronfeld. (4) Special General Courses and Group Courses every month. Apply Das Bureau der Wiener Arztekurse, Wien VIII., Schlösselgasse 22. The Society for the Study of Digestive and Metabolic Diseases are also meeting from Sept. 30th to Oct. 3rd. Inquiries to Prof. Dr. Fuld, Berlin W. 15, or to Dozent Dr. Lugen, Wien XI., Alserstrasse 4 (Klinik Ortner).

MANCHESTER BABIES' HOSPITAL.—The medical report for 1924 shows that 223 children were in the hospital during the year, the average period spent there being 54 days for all cases and 30·7 days for fatal cases. There were 36 deaths, of which 16 were due to pneumonia, 11 to dyspepsia, 3 to tuberculosis, 2 each to status lymphaticus and congenital heart disease, and 1 each to cerebral abscess and congenital syphilis. Two deaths took place within 48 hours of admission. Research on the use of oxygen administration in the treatment of atrophic infants has been continued, the results having warranted the provision of a third special cot. The new buildings were practically finished when the report was written. The new wards include sun parlours and verandahs opening into the garden on the south side. Not only can 80 babies be taken, instead of 50 as hitherto, but the X ray, massage, and mercury-vapour lamp departments, which have been handicapped by seriously cramped conditions, will now be able to work in their own special quarters, to the benefit of both patients and staff.

The Salvation Army Mothers' Hospital Extension.—The new buildings of this institution at Lower Clapton-road were opened by the Queen on July 16th, among those presented to Her Majesty being Lady Barrett, who is head of the medical staff. The hospital additions include two new bungalow blocks, which increase the accommodation from 60 to 90 beds. These blocks are models of sunny spaciousness, the approaches and adjuncts being built with an eye to the mothers' comfort and convenience and to the staff's fullest efficiency. Another important new feature is a specially designed and fully-equipped operating theatre—a feature the hospital has hitherto lacked and has greatly needed. Other departments of the hospital have been renovated and re-decorated, the total cost being £17,500.

Professional and Business Women's Hospital League.—The annual report for the year ending Dec. 31st, 1924, states that 518 new members (50 of them students) joined during the year, making the total number 2008. The schedule of sickness and disease recognised by the League includes all cases which a general hospital will admit, and excludes mental illness, infectious disease, rest cures, and cases not sufficiently serious to be admitted to hospital. The ordinary benefits available are: 1. Four weeks' treatment in a hospital specified by the committee, either in London or in the provinces. 2. Free consultation with a gynæcologist, should this be necessary. 3. A reduction of cost on surgical instruments. Grants have been given for massage, X ray treatment, surgical splints, and help towards the cost of instruments. Up to the present it has been found impossible to give grants for specialists' fees. The subscription is now *7s. 6d.* a year, and every member receives a numbered membership card. During the year 82 members underwent treatment at hospitals in London, 11 in the provinces; grants were made to 42 others. Fourteen applications were refused, 7 were considered ineligible, and 11 were withdrawn. The Secretary of the League is Miss P. Strachey, at 36–37, Marsham-street, Westminster, S.W. 1.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, July 27th, to FRIDAY, July 31st.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. A Special Course of Lectures, *including clinical* demonstrations upon selected cases, will be given at the Hospital at 5 P.M. as follows: Monday, Dr. Carnegie Dickson on The Pathology of the Cerebro-Spinal Fluid; Tuesday, Dr. Hildred Carlill on Lesions of the Cranial Nerves; Wednesday, Mr. Lindsay Rea on Ocular Manifestations of *Nervous Disease; Thursday, The* Registrar on Common Neuroses: and Friday, Dr. C. Worster-Drought on Clinical Forms of Neuro-syphilis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 27th.—11 A.M., Surgical *Registrar: Surgical* Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 3 P.M., Mr. Donald Armour: Operations.

TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 2 P.M., Mr. Addison: Operations. 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—11 A.M., Medical Registrar: *Medical Wards.* 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-*patients.*

THURSDAY.—11 A.M., Sir Henry Simson: *Gynæcological* Wards. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin *Dept.* 12 noon, *Dr.* Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY, August 1st.—10 A.M., Dr. Saunders: Medical Diseases *of* Children. 10 A.M., Mr. Banks-Davis: Operations of the Throat, Nose, and Ear.

Daily, 10 A.M. to 5 P.M., Saturdays, 10 *A.M. to* 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Appointments.

HAMILTON, W., M.B., Ch.B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Loanhead District of the County of Edinburgh.

Queen *Charlotte's Maternity* Hospital, Marylebone-road: LANKESTER, A. L., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officer.

Royal Chest Hospital, City-road, E.C.: GREENSLADE, C. M., M.B., Ch.B. N.Z., F.R.C.S., WILLIAMS, H. LESTER, M.B., Ch.B., F.R.C.S., Assistant Surgical Officers; and KERLEY, PETER, M.B., Radiologist.

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Sen. Res. Surg. £330. Jun. Res. Surg. £300.

Barnsley and Wakefield Joint Sanatorium.—Asst. Tub. O., &c. £450.

Birmingham Cripples' Union and Royal Orthopædic and Spinal Hospital.—Jun. H.S. £150.

Bournemouth, Royal Victoria & West Hants Hospital.—Hon. Med. Clin. Asst., Surg. Clin. Asst., Ophth. Clin. Asst. Also Hon. Asst. S. and Hon. Asst. P.

Brighton, Lady Chichester Hospital.—H.P.

Brighton, New Sussex Hospital.—Temporary Dental Surgeon.

Bristol, Cossham Memorial Hospital, Kingswood.—Res. M.O. £150.

Cairo, School of Dental Surgery.—Supt. and Lecturer in Metallurgy, &c. £E.600. Lecturer in Surg. £E.480. Asst. Lecturer in Surgery. £E.360. Lecturer in Mechanics. £E.480.

Cumberland and Westmorland Mental Hospital, Carlisle.—Jun. Asst. M.O. £350.

Hertford County Sanatorium, Ware Park, near Ware.—Asst. M.O. £350.

Hong Kong University.—Reader in Biology. £600.

Liverpool County Borough.—Jun. Asst. Sch. M.O. £600.

Liverpool, Royal Children's Hospital.—Two Res. H.P.'s and Two Res. H.S.'s. Each at rate of £80.

Liverpool University.—Professor of Entomology. £800.

London Hospital, E.—First Asst. and Reg. £200 for six months.

London School of Hygiene and Tropical Medicine.—Lecturer on Tropical Hygiene. 200 guineas.

Manchester, Ancoats Hospital.—Pathological Registrar. £100.

Manchester Royal Infirmary.—Second Surg. Reg. £150.

Ministry of Pensions.—Part-time Surgical Supervisor of Orthopædic Clinics. £500.

Mount Vernon Hospital, Northwood, Middlesex.—Surg. Laryngologist.

Pietermaritzburg, Grey's Hospital.—Male H.S. £500.

Rochester, St. Bartholomew's Hospital.—H.P. at rate of £200.

Royal Chest Hospital, City-road, E.C.—Asst. Tub. O. £550.

Royal Northern Hospital, Holloway, N.—Anæsth. £10 10s.

Salford Royal Hospital.—Radiologist. £300.

Samaritan Free Hospital for Women.—H.S. at rate of £100.

Staffordshire Mental Hospital, Cheddleton, Leek.—Jun. Asst. M.O. £350.

Sudan Government, Wellcome Tropical Research Labs., Khartoum.—Asst. Bacteriologist. £720.

Willesden General Hospital.—Hon. Anæsth.

Worcester General Infirmary.—Jun. Res. M.O. £120.

Births, Marriages, and Deaths.

BIRTHS.

ANDREWS.—On July 10th, at 152, Harley-street, W. 1, to Helen, wife of J. Alban Andrews, M.C., F.R.C.S.—a daughter.

DICKSON.—On July 21st, the wife of W. Muir Dickson, F.R.C.S., of a daughter.

LOCK.—On July 17th, at Glyngarth, Soho-hill, Birmingham, the wife of J. Lewis Lock, M.A., M.B., of a daughter.

MOODIE.—On July 15th, the wife of Dr. William Moodie, of Horton, Epsom, of a daughter.

NORMAN SMITH.—At "Stone Field" Maternity Nursing Home, Kidbrook Grove, Blackheath, on July 15th, *to Molly* (née Terraine), wife of Dr. Norman F. Smith (Khartoum), the gift of a daughter.

RAVEN.—On July 11th, at Victoria-parade, Broadstairs, the wife of Martin O. Raven, M.D., of a daughter.

WATSON.—On July 18th, at Del Rey House, Cheltenham, the wife of Lieut.-Colonel C. H. Watson, D.S.O., I.M.S. *(retd.)*, of a daughter.

MARRIAGES.

STUTTAFORD—ROYDEN.—On July 16th, at the Parish Church, Flegg Burgh, Norfolk, W. J. E. Stuttaford, *M.C.*, M.R.C.S., L.R.C.P., to Marjorie, only daughter *of Dr.* and Mrs. Royden, of Flegg Burgh.

WAKELEY—NICHOLSON-SMITH.—On July 21st, at St. Margaret's Church, Lee, S.E., Cecil P. G. Wakeley, F.R.C.S., of 5, Devonshire-place, W., to Elizabeth Muriel, *only* daughter of Mr. and Mrs. James Nicholson-Smith, of Blackheath.

DEATHS.

BEDDARD.—On July 14th, Frank Evers Beddard, D.Sc., F.R.S.

DUNCAN.—On July 15th, at Margate, Horace Duncan, B.A. Camb., M.B. Lond., son of the late *James Duncan, M.D.*, of Henrietta-street, Covent Garden, London, in his 64th year.

EVANS.—On July 18th, at Danygraig, Burry Port, Surg.-Lieut.-Colonel Evan Evans, T.D., M.B., F.R.C.S., D.P.H., of Llanelly, in his 72nd year.

FRY.—On July 14th, at his residence, Old Town, Clapham Common, John Marchant Fry, L.R.C.P. Lond., in his 62nd year.

HENDRIKS.—On July 17th, at Bicester, Cecil Morgan Hendriks, O.B.E., M.B., M.R.C.S., in his 70th year.

WILLIAMS.—On July 13th, at Colwyn Bay, W. M. Venables Williams, L.R.C.P., L.R.C.S., D.P.H., J.P., in his 68th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts

INFECTION BY BOOKS.

By J. E. McCartney, M.D., D.Sc. Edin.,
DIRECTOR OF RESEARCH AND PATHOLOGICAL SERVICES, METROPOLITAN ASYLUMS BOARD.

The method of spread of infectious disease is a subject of great importance, particularly from the point of view of prevention, and in order to ensure that an epidemic shall be properly controlled all the various methods of its dissemination must be considered.

Owing to the lack of knowledge of the biology of the causal agents of certain infectious diseases it is very difficult, if not impossible in many cases, to state whether the infective agent is present in an active state or not. It is obvious that the answer to such a question is of supreme importance, for if the virus is active then vigorous steps must be taken for its destruction, whereas if the causal agent of the disease is inactive then there is no dnger of the infection spreading.

The Problem.

A possible means of spread of infectious disease is by means of books—particularly library books. Briefly, the problem is as follows: A book has been borrowed from a public library and is taken to a house in which infectious disease is either present at the time or occurs while the book is there. The book, which may or may not be read by the patient, is returned to the library and is almost immediately taken out by another person to a house in which some of the inmates are susceptible. Is there a danger of infectious disease being carried from the one house to the other by means of the book? If books do carry infection then the possibility of spread of infectious disease may be great owing to the wide circulation which a public library enjoys. The precautions necessary for the prevention of such a means of spread must be thorough, involving the expenditure of much time and money. If, on the other hand, the chances of spread of infection are minimal, then the energies of those responsible for the control of disease can be expended more profitably in closing the known avenues of spread.

Various Possible Infections.

Of the infectious diseases *small-pox* must be considered separately owing to its virulent nature. Some observers have recorded instances where it would appear that small-pox has been conveyed by books and by letters, but this method of spread has not been conclusively proved. Although the virus of small-pox is comparatively short-lived outside the body, yet the amount of virulent material necessary for infection is extremely small, and while the chances of disseminating small-pox by means of books are not great, yet we must assume, in the absence of definite information, that there is always the possibility of such spread. This information could only be obtained by extended human experiment, which is, of course, out of the question.

Owing to the virulent nature of the disease and the dire consequences of its spread, no risks whatever can be taken with small-pox, and in the light of our present knowledge all books, letters, papers, &c., must be considered as potential means of conveyance of small-pox infection and should be rigorously destroyed.

With regard to exanthematous diseases such as *measles*, *rubella*, and *chicken-pox*, our knowledge of the nature of the infective agents is extremely scanty. The biology of these viruses is unknown and their period of survival outside the body can only be conjectured. It is not possible to transmit any of these diseases to animals, and in consequence experimental work is out of the question, and precise facts as to infectivity could only be obtained by carefully controlled investigations on the human subject. It is known, however, from clinical observations that these viruses are extremely short-lived outside the body, and their period of infectivity under these conditions is probably only a few hours. It is also known that the virus, in the case of measles and rubella, is present in the naso-pharyngeal secretions, and in order definitely to infect a book, the patient would have to be in the early stages of the disease and to cough or sneeze thoroughly into its pages. From our available knowledge it would appear that even if the book were infected with virulent material, the viruses would die out in a comparatively small time, and that the chance of spread of infection by this means is remote. No definite evidence has been produced, as far as we know, that measles, rubella, or chicken-pox has been transmitted through the agency of books.

Scarlet fever, though an infectious disease, is nothing like so infectious as measles. The naso-pharyngeal secretion is infective, and the causal agent may be disseminated by coughing and sneezing. If the ætiological agent of the disease is as recent work would indicate, the streptococcus, then it is known that this organism will survive drying only for a short time, and even if found viable outside the body, may not necessarily be virulent.

Investigations could be made on the period of survival of the streptococcus in infected books, and the length of time the organism is viable under the conditions under discussion could be ascertained.

In *diphtheria* the causal organism is known and its period of survival outside the body has been determined. Dried diphtheria membrane kept in the absence of light has been found to contain living virulent bacilli after several months, but that the organism would survive for that length of time under the usual conditions in which a book becomes infective is doubtful. The fact remains that books have not been definitely proved as a source of transmission of diphtheria, and if transmission does occur it is difficult to prove.

Limits of Our Knowledge.

There are numerous methods of spread of infectious disease, many of which we do not know, and a possible means is not necessarily the probable one.

The question of spread of infection by books was recently discussed by the Society of Medical Officers of Health.[1] The general opinion was that there was no knowledge that infection was conveyed through books, but in the light of uncertainty definite measures should still be taken to prevent the possibility of spread of infection.

This summary indicates the view that must be taken in consideration of the meagre knowledge we possess regarding the spread of infectious disease. Apart from small-pox, the chance of infection by books is extremely small, but the medical officer should take no risks and should deal with the books as if they were infectious. In conclusion, it may be stated that it is extremely improbable that library books play an active part in the dissemination of infectious disease.

HEALTH AND HOMECROFTING.

The close connexion which exists between the food of the people and the public health gives a scheme of homecrofting put forward by Prof. J. W. Scott an important medical aspect. The scheme has been clearly explained in a recent booklet.[2] Opportunity has now arisen for putting it to a practical test on the outskirts of Cheltenham; and Mr. J. St. Loe Strachey in the *Spectator* of July 11th has given the project his wholehearted support.

Homecrofting is in essence organised allotment gardening where each artisan dwelling has attached to it about one-third of an acre of land. At first the way to cultivate the land is taught by a skilled overseer, but each tenant should soon by his own labour be able to become independent of the greengrocer. The scheme plans for older school-children to be sent in rotation every third week to be taught homecrofting; how to prepare and manure the land; what succession of crops to sow; how to keep and feed rabbits, fowls, goats, and perchance a pig. Each time they return they would see the progress since they left and so be able to appreciate the value of their work. Thus a future generation would be educated for becoming scientific homecrofters, practising "subsistence agriculture," instead of being merely industrial consumers of food imported from abroad.

"Homecrofting," writes Prof. Scott, "is the art of making your own food with your own hands, so that you do not need to buy it. The suggestion is, take advantage of the short industrial hours. Aim at two shifts a day for the man: one shift at industrial work, earning wages, and another shorter shift, with his wife and children in his garden, producing food.

"A final way of escape from hunger. Wherever you have that you have a solution of the unemployment problem. That is what the homecroft plan tries to present."

In these days of short working hours and unemployment this scheme presents an ideal method for filling up leisure time. No form of recreation is healthier or more interesting than gardening. No vegetables ever taste so good as your own; no eggs are ever so fresh. *Nevertheless*, the plan is put forward, in the main, not for health purposes, but for economic and social reasons.

The first trial is to be on 18 acres, if the needed capital, £2500, can be raised. As the money will be invested in land and cottages, contributors, even if the experiment fail totally, will not lose all they invest. It is a worthy attempt to do something to rectify present social and industrial difficulties. The *Spectator* undertakes to receive and pass on any subscriptions and is offering prizes to the best homecrofters.

An Address

ON

PERSONALITY, MAGIC AND MEDICINE.

Delivered before the University of Edinburgh at the Graduation Ceremony, July 24th, 1925,

By GEORGE M. ROBERTSON, M.D.,
F.R.C.P. Edin.,

PROFESSOR OF PSYCHIATRY IN THE UNIVERSITY OF EDINBURGH.

Vice-Chancellor,—My first duty is a very pleasant one. It is to congratulate those who have to-day achieved the high honour of becoming graduates of this University. In a short time many will be engaged in practising medicine, and others will have scattered to distant parts of our wide Empire. In the name of the University, I wish you all God-speed! Your course of professional study has been a long and arduous one, and during it you "scorned delights and lived laborious days." Do not take this too literally, for Promotors, like poets, enjoy a certain licence. I have no doubt that many of you, without detriment to your studies, have found time "to sport with Amaryllis in the shade." Gone, alas! are "the tangles of Neæra's hair." Since Milton wrote these lines fashions have changed.

Examinations and Personality.

You have all known what it is to suffer under the dark shadow of professional examinations. Such anxiety is a deadly poison to intellectual effort, but you have found an antidote in the magic of the Vice-Chancellor's touch, and of the cabalistic words which he has pronounced over every graduate. These graduation rites, however, are much inferior in picturesqueness and romance to those of a bygone age. A thousand years ago, at the famous medical school of Salerno, the Chancellor, or Rector, placed a crown of laurel on the brows of the successful graduate. Then he placed a ring on the graduate's finger. And finally, to mark the climax of the proceedings, the learned professors kissed the graduate. Even in those far-off days there were lady medicals!

No one has a good word to say about examinations. They are disliked by the professor who examines only less than by the student who is examined. They seem to be a sort of old-man-of-the-sea, of Chinese descent, who has fastened himself on the shoulders of our academic life. The Chancellor of the University, Lord Balfour, calls them "soul-killing institutions, bad for the teacher and bad for the taught." Now, if they are absolutely necessary in order to test your fitness for the practice of medicine, is it not strange that no test is applied to that which is the master-key to success as a physician—namely, "personality?" It is difficult to say what this personality is.

Personality is described by some in poetical language as personal magnetism. By others it is regarded as a miraculous gift of divine origin, the gift of healing. We are assured on the testimony of good people, like bishops, that there are persons, quite unequipped with any medical knowledge, indeed one might correctly say unhampered by any medical knowledge, who work miracles of healing. Such gifted beings are called "healers" in order to differentiate them from medical men fashioned of common clay, whose little learning has been laboriously acquired, and whose power of healing, unlike theirs, is subject to definite limitations. The difference in the methods employed by the healer and by the doctor is that which exists between magic and science. As the philosophy of healing is obscure let us investigate for a few minutes the problems connected with magic and medicine, giving, of course, the place of honour to magic, by right of seniority.

There is no Chair of Magic in the University of Edinburgh. This is most unfortunate, because, a knowledge of the history of magic helps us to understand the development of the human mind and also of science. Who can tell what chemistry owes to the search for the Philosopher's Stone—and pharmacology to the pursuit of the Elixir of Life? The Earl of Gowrie, who was killed in 1600, studied magic at Padua, but whether he did so in intra-mural or extra-mural classes we are not told. Sir Walter Scott, however, informs us that at the University of Toledo there was a Chair of Necromancy. Although there is no special Chair of Magic in Edinburgh, this important subject probably survives in one or another of the existing chairs. In the Faculty of Arts, the Chair of Natural Philosophy includes much that would have been regarded at one time as magic. Consider the applications of electricity alone. Last year when Wembley was opened thousands of persons in Princes-street Gardens heard a voice from the clouds repeating the Lord's Prayer, and then another voice, that of the King, addressing the people. Had King James VI., who founded this University, been present on this occasion, he would most certainly have regarded these as manifestations of a magical character, for he held strong views on witches and witchcraft.

Magic in the Medical Clinic.

In the Faculty of Medicine magic under a disguise is to be found. The preservation of life by insulin and the painless sleep of chloroform are in a sense magical. The protection from typhoid of millions of our fighting men during the war was in a sense as magical as the action of Moses when he made a serpent of brass, and it came to pass that all who beheld the serpent lived. Magic consists not only in the performance of rites invoking occult agencies, not only in the employment of materials possessing supernatural power and virtue, but also in a certain habit or attitude of mind towards inexplicable phenomena. Now, there exists to-day a curious and most amazing difference in the way that people have of looking, on the one hand, at phenomena of a physical kind, and on the other, at phenomena connected with the treatment of disease, a distinction actually fostered by the Church. No educated person now believes that the applications of physics are magical. They merely illustrate the progressive unveiling of the forces of nature and their subjugation to the uses of mankind. But it is not so with regard to the employment of remedies in disease. The element of magic in this sphere has never disappeared. No theory of disease is too fantastic, no line of treatment too futile to be accepted even by the most cultured. The sick person has some excuse for his actions and beliefs as he is never at his best; he is always off colour. He is more emotional and more suggestible. He is an easy prey to fears of ill-health, and he clutches eagerly at any remedy that chance brings within his reach. His mind is in an ideal condition to be worked on by magic. In colloquial language, "he is simply asking for it."

Let us see how readily the symptoms of disease lend themselves to treatment by magical methods. However unpleasant symptoms may be to the patient, almost all pass away naturally in course of time. And, if we exclude physical conditions, such as broken bones, we find that symptoms are almost exclusively mental. Pain is the basis of every symptom; malaise and discomfort are merely lesser varieties of it. And pain is a simple state of mind, just like the sensation of colour. It seems to be felt in a particular region of the body, just as colour seems to be the property of an external object, but both the sensation of pain and the sensation of colour are experienced within the brain and in the mind. Because of this localisation of

5318

sensation within the brain, pain may still seem to be felt in the foot, although the whole leg has been amputated.

Pain is sometimes called real and sometimes imaginary, but to the patient both forms are real and both forms are amenable to treatment by mental suggestion, whether magical or otherwise. Toothache, for example, due to an organic cause, such as the decay of a tooth, is of course "real" pain, as we can all vouch for, yet it sometimes happens that when the hand of a patient suffering from toothache touches the dentist's front door bell all pain suddenly vanishes. Suppose now that a patient desires treatment of a magical kind. He may go to a Christian Scientist or to a Spiritual Healer; he may consult a plausible charlatan; or he may seek the vendor of a secret nostrum. In many cases he will benefit: and why not? The majority of symptoms pass away spontaneously; the treatment he receives is mental and therefore suits the symptoms exactly; mystery is invoked and this appeals to the superstitious elements lying latent in the patient's mind; and lastly, the patient comes with a child-like faith in the treatment for which he asks. As honest seekers after the truth we must face these facts. Look at Christian Science and its incredible development in America. It is a very simple therapeutic system, from which diagnosis is excluded, and it employs one remedy. Painfully inadequate as it seems to us, it has succeeded in founding cathedrals and in comforting millions. It has built 74 churches in this country and hundreds in America. Would that some of the money thus subscribed by grateful patients had found its way into the empty coffers of this University! Why do we not receive this grateful help? Is it because we have concerted healing into a cold science instead of leaving it an impressive mystery and a passionate faith? For it has passed through those phases. Have we like Martha been careful and troubled about many things, material, but missed the one thing, psychic, that is needful? Men and women hunger after the mystic and the wonderful; they are just big children in matters connected with illness; and their craving for miraculous cures will not cease till the progress of the science of medicine has rendered such cures superfluous.

The patient may consult a regular practitioner of medicine, and what follows? Almost inevitably the doctor will prescribe certain vegetable or mineral products, and the patient will derive benefit from his prescription. Is this almost exclusive reliance on the physical action of drugs, when we know to what an extent symptoms are mental, either logical or scientific? How much of it is due to a mere desire to gratify the patient's faith in medicine out of a bottle? Or is it unconsciously derived from the pursuit of the "elixir of life"? We all know that traditions die hard, as witness the obsolete prayer to Jupiter, concealed in the symbol that heads our prescriptions. Drugs undoubtedly possess pharmacological actions which are invaluable, as, for example, the effect of quinine in malaria, but symptoms are mainly mental, and medicines largely depend for the benefits they confer on the confidence of the patient in the physician and faith in his prescription. If this be so, then the drug treatment of minor ailments does not differ so very much from those other forms of treatment that consist merely of mental suggestion, though called by another name.

THE POWER OF THE MIND.

What distinguishes the doctor from the healer is his undeviating rationalism. His recognition of the mental element in disease, whether as a cause, as a symptom, or as a cure, is deficient. He has a horror of introducing mystery into his treatment, even though his patients have not yet emerged from the darkness of superstition, and his practice would probably increase if they believed that the letters M.B. after his name indicated that he was a Bachelor of Magic. And he could always assure for himself and his family a respectable livelihood among the credulous, who form the majority of the population, if we could honestly assert that the letters Ch.B. were conferred upon him because he was a Bachelor of Charlatanism. It is not in the alleviation of symptoms, nor in the treatment of minor ailments, that medicine impresses us. It is in its confident challenge to the diseases that kill that the science of medicine reveals its greatness. Witness the attack on cancer, and the results just obtained by a graduate of this University. What also could be more convincing, what more impressive, than the simple statement that during our life-time the death-rate has fallen from 22 per 1000 to 12, and that the expectation of life has risen from 40 years to 55. The people of this country and of this generation have, through medical science, experienced in their own persons the fulfilment of the promise conveyed by the Prophet Isaiah to the dying Hezekiah: "I have heard thy prayer, I have seen thy tears: I will add to thy days 15 years."

Recoveries are effected by magical methods, by religion, by charlatanism, and by nostrums. The importance of these is not to be minimised because they occur in minor ailments, for once a neurosis or other illness has begun, no one can foretell how serious the end-results may not be. The medium of cure in all these cases is the mind. The body cannot get away from it any more than the body can escape the action of the force of gravitation. Its power is great both as a causative and a curative agent. It can produce organic changes; it can hasten or retard recovery.

At the beginning of the Christian era, the science of medicine was in its infancy among the Jews, who believed that disease was directly inflicted by God or caused by evil spirits. In this, the twentieth century, can science accept such primitive pathology? The sphere of the Church is spiritual and moral; and the clergyman is honoured in every household and welcomed in times of sickness and of sorrow. But the healing of the sick is the sacred trust of the physician, as absolutely so as the study of the heavenly bodies in their courses is the sphere of the astronomer, although Science can never forget that the Church did not concede even this point till Galileo had suffered.

THE MOST VALUABLE ASSET.

In the last place, the most valuable asset of the physician is personality. Its influence in sickness is mental healing, and it is of greatest value when trained and directed. The methods of employing such healing are infinite, for they vary with age and sex, with race and religion, and with circumstances.

Unquestionably, you, who have graduated to-day, are members of the only class fit to be trusted with the exercise of these great powers of healing. Your Alma Mater relies upon you because she knows that you possess a knowledge of the science of medicine, and because you follow the highest ideals of professional conduct. The superstitious and the ignorant are drawn, as by a magnet, into the pitfall of charlatanism.

Although you have passed no professional examination on this subject, you all have within you a psychic influence more powerful to relieve and more helpful in sickness than all the drugs in the British Pharmacopœia. This magical force is personality. It is this possession that makes medicine greater than a science: Go forth and use it wisely!

THE LATE DR. J. T. WILLIAMS.—The death occurred on July 16th at Barrow-in-Furness of John Terrell Williams, M.R.C.S., at the age of 80. He was the oldest member of the profession in Barrow. A student at St. Bartholomew's Hospital, he qualified in 1867, and held a house appointment at his hospital before becoming resident medical officer at Rossall School. For many years he was honorary consulting surgeon to the North Lonsdale Hospital. He was made a J.P. in 1890.

THE

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF MUSCLE TONE,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

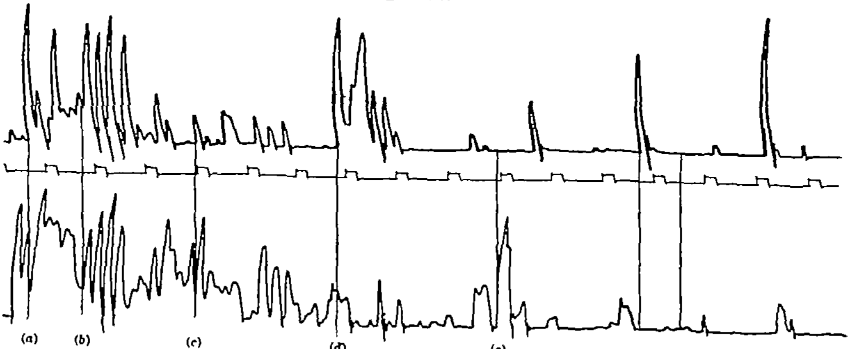
BY S. A. KINNIER WILSON, M.D., B.SC. EDIN., F.R.C.P. LOND.,
PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE IV.*

ATHETOSIS.

MR. PRESIDENT AND GENTLEMEN,—As with chorea, so with athetosis, a typical case is *easy of recognition*, though to define the symptom is not equally simple. In 1871 Hammond, who first drew attention to it, stated that "it is mainly characterised by an inability to retain the fingers and toes in any position in which they may be placed, and by their continual motion," and in another passage he said that "the movements are slow, apparently determinate, systematic, and uniform," *in contrast to those of [post-hemiplegic]* chorea, which are "irregular, jerking, variable, and quick." The contrast between the two, however, is by no means so definite as this description might lead one to suppose.

FIG. 27.



Athetosis. Upper record, contractions of left extensor communis digitorum: lower, left flexor longus digitorum.

CLINICAL CHARACTERS.

(1) Athetoid movements are characterised by relative slowness, in apparent contrast with the relative rapidity of choreic movements, and by the perpetual blending of one movement with another, leading to the "continual motion" of Hammond. They form a mixture of irregularly synchronous contractions of opposite muscular groups, so that on occasion the limb or a segment of it is immobilised momentarily in an attitude. The "mobile spasm" flows indifferently into muscular units, the result being a medley of contraction entangling the limb, as it were, and leading to no accomplishment.

During this irregular muscular display varying rigidity naturally makes its appearance, yet unless the athetosis is associated with some degree of "paralysis" there is *little*, if any, actual fixed *rigidity*, and this generally bears some proportion to the amount of "paralysis." In fact, during temporary relaxation of *athetotic activity the limb musculature is* frequently, if not constantly, hypotonic. "Voluntary" innervation of the affected part is always laborious and commonly aggravates the athetoid contractions, at least within a very short period; "voluntary" control over them is fleeting and imperfect.

(2) Closer analysis of the exact nature of athetosis can be made conveniently by means of double tambour tracings, care being taken by adequate limb fixation to ensure the absence from the record of *fortuitous (non-athetoid) movements*. *Fig.* 27 reproduces a tracing taken from the left forearm in a striking case of adult athetosis (of vascular origin, and progressive); the upper tracing represents the contractions of the extensor communis digitorum, the lower, of the flexor longus digitorum. At (*a*) practically synchronous contractions of these opposite muscles occur; at (*b*) a series of four similar concomitant contractions is seen; between (*c*) and (*d*) *flexor activity is more pronounced than extensor*; at (*d*) the extensor group contracts vigorously during flexor contraction; and at (*e*) flexor contractions take place by themselves. The irregularity of the individual contractions of one implicated muscle is well-shown in Fig. 28 (from the same case), recording the innervation of the long finger flexors during a period of extra-excitability. Here contraction follows *contraction in an extremely confused fashion*, one *being often thrown in before the muscle has relaxed* from the previous contraction. Fig. 20 records simultaneously the contractions of the biceps brachii and triceps of the same case; it shows, between (*a*) and (*c*), three contractions of the biceps *to one* (tripled) of the triceps; at (*b*) reciprocal innervation *is completely in default; at (c) flexor and extensor* contractions are almost but not quite synchronous; at (*d*) the triceps contracts and a little later the biceps, both relaxing together; and at (*e*) the former contracts in four quick innervations by itself.

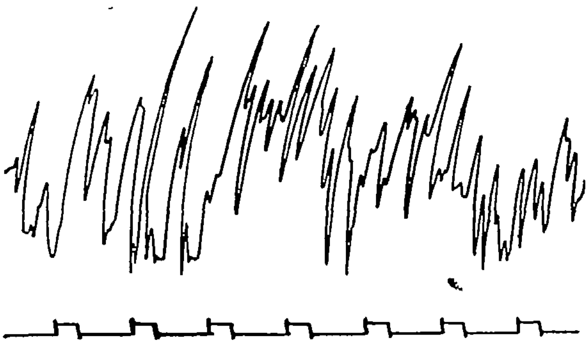
Another series of records have been taken from a case of right infantile cerebral hemiplegia, with athetosis and Jacksonian *epilepsy*. *In this case I have* made use of the extensors of the wrist and fingers, the former normally relaxing (after synergic contraction during closure of the fist) when the fingers are extended.

---

* Lectures I., II., and III. appeared in THE LANCET of July 4th, th, and 25th respectively.

In Figs. 30, 31, and 32 are represented three different results obtained from this patient; in Fig. 30 the wrist extensors relax more or less normally while the finger extensors contract, but they contract again in a quite abnormal fashion, notwithstanding the maintained finger extension; in Fig. 31 the wrist extensors decontract appreciably before the contraction of the finger extensors; in Fig. 32 the finger extensors contract normally, yet the wrist extensors hold their contraction for a time, then at length relax, but contract once more. Such modifications of physiological law are quite beyond the power of "volition" to effect. Nothing could more conclusively demonstrate the complete abrogation by disease of the normal physiological interaction of component muscular units in the performance of a given movement, and this interference with physiological law is entirely characteristic of the movements of athetosis. In paralysis agitans, as we have seen, the law is not annulled.

FIG. 28.



Same case as Fig. 27. Contractions of left flexor longus digitorum during a period of extra-excitability.

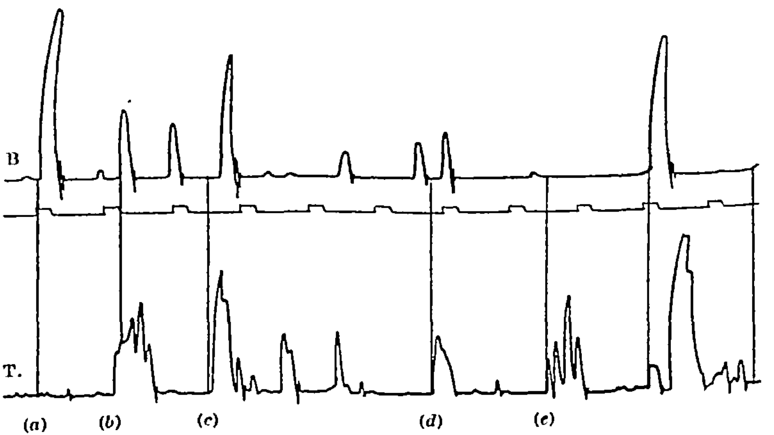
(3) Owing to the essential variability of athetotic contraction no enduring posture might perhaps be expected, yet the "athetoid hand" is sufficiently definite to merit attention. A saddle-shaped posture of the fingers is common, the terminal phalanx being in flexion while the proximal phalanges are in extension; with this extension (often hyperextension) at the metacarpophalangeal joints is coupled a notable flexion at the wrist, so that the hand often assumes that attitude of wrist and fingers which we have seen is of extreme frequency in chorea and which, as we have also seen, represents a "physiological shift" from the posture of the normal hand at rest. In athetosis, further, a tendency for pronation or hyperpronation of the forearm (the "pronator sign") is equally common.

(4) Comparing, now, the symptoms of chorea and athetosis, we find the resemblances more impressive than the differences. In respect of the latter, we have seen that choreic movement is discrete and rapid, while athetoid movement is slow and confluent. But this difference is more apparent than real; athetoid action is slow largely because it is confluent, and, on the other hand, confluent chorea results in slowing of the "spontaneous" movements. Besides, in some athetoses a degree of discreteness and quickness is observable. In respect of resemblances, in each the type of motor derangement is complex, elaborate, and specialised; changeableness and variability of movement is a prominent trait (i.e., absence of essential repetitiveness); the law of reciprocal innervation is at fault in athetosis and in confluent chorea equally; the movements, "caricatures" though they are in athetosis more than in chorea, have the appearance none the less in the case of the former of being subjectively purposeful—as for grasping or relinquishing an object, &c.—though they are objectively purposeless. In both, a degree of hypotonia is commonly discoverable; resemblances between the athetoid and the choreic hand are sufficiently obvious; involvement of the mechanism for emotional expression, if found in athetosis, is commonly bilateral, as in chorea, though to this there are exceptions. It is difficult to gauge the amount, if any, of actual weakness of the musculature in athetotic cases, since (*a*) they are not infrequently accompanied by definite corticospinal derangement (hemiplegia or hemiparesis), from which it is desirable to attempt to separate the athetotic element; (*b*) "volitional" innervation is constantly impeded by athetoid activity, rendering distinction arduous. Enough, however, has been said to justify fully the common grouping of choreic and athetotic movement under the general heading of "choreo-athetosis."

RELATION OF ATHETOSIS TO TONIC INNERVATION.

(5) The condition described as "tonic innervation" is constituted by inability to relax "voluntarily" a given innervation initiated by that process. As the patient "voluntarily" contracts his flexors (say) in movement active inhibition of the antagonists, the extensors, takes place, according to the law of reciprocal innervation; when next he would reverse this movement, he is able "voluntarily" to innervate the extensors, but no corresponding inhibition of the flexors takes place; these remain contracted, it may be for many seconds. From what we have been able to show by clinical methods, a condition resembling tonic innervation, in fact practically identical with it, may occur in athetosis. I have a number of observations confirming this statement, which, for that matter, was fully exemplified in a paper on "The Phenomenon of Tonic Innervation." The symptom was then described as occurring in cerebral cases (frontal) unassociated with athetosis, and as being seen mainly if not solely during so-called "volitional" movement. In the case of athetosis it is found, when present, during so-called "involuntary" activity, in the sense that antagonists may remain definitely contracted though the opposite muscles are rising into contraction, but it often also develops in typical guise during "voluntary" movement. I have already commented on the fact that no phenomenon of this kind has come under my notice in any of the scores of Parkinsonian cases that have been personally investigated.

FIG. 29.



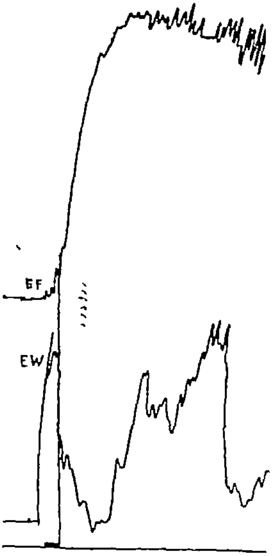
Same case. Contractions of biceps and triceps.

Clearly, it can only be explained satisfactorily by regarding it as a derangement in the proper relation between impulse and inhibition—i.e., as a disorder *of reciprocal innervation.* Thus our clinical study of athetosis leads us again to the view that its essential and underlying basis is precisely this interference with the normal laws governing the physiological interaction of component muscular units in movement, and it is immaterial whether this be "voluntary" or "involuntary," for no discriminating line can be drawn between the two.

On the sensory side, there was complete astereognosis in the right hand, with only slight diminution in the appreciation of tactile stimuli.

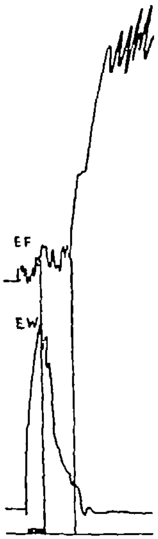
Apparently, an exhaustion paresis of the right corticospinal system made the athetosis temporarily impossible; only with recovery of power did it begin again. The evidence in this case pointed unmistakably to a *cortical* origin for all the symptoms.

FIG 30.



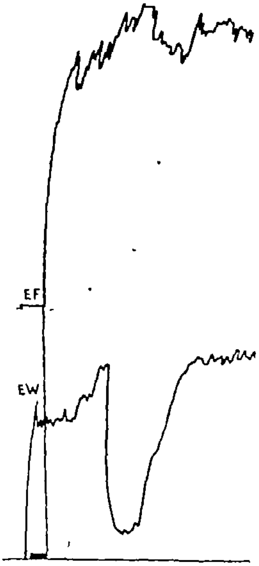
Athetosis. Abrogation of physiological law during *movement of extension* of the closed fingers: extensors of wrist decontract but contract again.

FIG. 31.



Same case as Fig 30. Decontraction of wrist extensors before finger extensors contract.

FIG. 32.



Same case as Fig. 30. *Wrist extensors* fail at first to decontract when finger extensors contract: after later relaxation they contract again.

PATHOGENESIS OF CHOREO-ATHETOSIS.

On the clinical side, evidence has been adduced indicating, both for chorea and for athetosis, that the following considerations bear on the problem of pathogenesis.

(1) Since the movements are active and continuing, for their existence relative integrity of some efferent path is a *sine qua non.* Many cogent arguments suggest that this path is the corticospinal path. I may refer the reader, for a moment, to the summary of the clinical analysis given at the close of the sections on chorea, and supplement the deductions there drawn by one or two more matters bearing on the topic.

Many cases of infantile cerebral hemiplegia with Jacksonian fits are accompanied by athetosis. We assign the hemiplegia and the epilepsy to encephalitis of the cortex and implication of the corticospinal tract, and it is justifiable and reasonable to assume in these cases a cortical origin for the athetosis also. Take a single illustrative case.

A little girl of 14 had suffered from infantile cerebral hemiplegia with athetosis and Jacksonian epilepsy since she was one year old. The aura to the fits was the appearance of "twinkling red, blue, and white lights" in the right field, followed by twitching in the right face and right fingers, which spread in typical Jacksonian fashion. For 20 minutes after each fit all athetosis disappeared from the right limbs.

I refer next to the case recorded by the late Sir Victor Horsley in his Linacre Lecture of 1909. A youth of 15 had had left hemiplegia with severe athetosis since an attack of scarlatina at the age of 7. Horsley found at operation that the right postcentral gyrus was reduced to half its normal size—a very significant observation. He excised the cortical motor area for the left arm, and the athetosis thereafter vanished entirely and had not returned when the patient disappeared from notice some 14 months later. On the other hand, the arm paralysis following the cortical excision had by that time been greatly mitigated. Similar cases have been put on record by Anschütz and others. Reference, too, may be made to Case XVIII. of Jakob's recent monograph, where left-sided athetosis disappeared entirely after a sudden left flaccid hemiplegia. The patient lived for 18 months after, but the athetosis never returned. (I venture to differ altogether from Jakob as regards the interpretation put by him on the pathological findings in this valuable case.)

Strong additional evidence is hereby furnished of the significance of *relative* integrity of the pyramidal system for chorea and for athetosis. I have never yet found a case of either in which "spontaneous" movements occurred in the presence of absolute corticospinal paralysis. No movements remotely resembling either have been seen in my clinical cases of decerebrate rigidity in man, and Magnus, similarly, has commented on their absence in his experimental animals (of various species) submitted to decerebration.

(2) Another line of clinical evidence points to the possibility of implication, in choreo-athetotic cases, of afferent paths to the cerebral cortex—viz., from the cerebellum by the regio subthalamica to the optic thalamus, whence there is a wide distribution of fibres to the pallium.

The frequent appearance of muscular hypotonia both in chorea and in athetosis has been mentioned above, and the element of incoördination is prominently in the clinical picture in both, especially, as concerns chorea, in the case of the confluent variety. In numerous instances of chorea the knee-jerk exhibits that "pendular" quality which pertains largely to cases in which cerebellar function is disordered. Now one of the many interesting facts connected with cerebellar dysfunction is, that whether the lesions be on the afferent side to that organ (spinocerebellar), or intracerebellar (cerebellar cortex, or from that cortex to cerebellar ganglia), or cerebellifugal (cerebello-cerebral), the same sorts of symptom to some extent make their appearance in each instance. It is impossible to say by clinical scrutiny alone of a case of cerebellar ataxia in which of these three divisions the lesion is situated. Hence where for other reasons a cerebellifugal (cerebello-cerebral) lesion is likely, we may well expect to find some kind of cerebellar symptoms. If, then, other clinical facts argue a cortical origin for a symptom-complex, the coexistence with it of certain cerebellar symptoms can justifiably be set down to the development of a cerebello-cerebral defect of function.

In other papers I have on more than one occasion laid stress on the many clinico-pathological cases which point to lesions somewhere on the cerebello-mesencephalo-thalamo-cortical apparatus being responsible for the appearance clinically of choreo-athetosis. The reality of "Bindearmchorea" (superior cerebellar peduncle, especially in the neighbourhood of Wernekinck's commissure) is fully established. In several cases of acute thalamic lesion (neothalamus) I have seen pronounced "involuntary" movements of the choreo-athetotic variety. I have in a recent case of "athétose double" found bilateral lesions of the neothalamus (posterior inferior region). A case at present under my care at Queen-square exhibits the thalamic syndrome with athetosis of the same limbs (arm in particular). I might also cite recent experimental work strongly favouring the view here maintained (Lafora), and the older and seemingly forgotten experiments of Bickel and Jakob, who produced so-called "cerebral sensory ataxia" by extirpation of the postcentral cortex, and who specially remarked "the peculiarly explosive character of voluntary movements" after the lesions. This, needless to say, is in fact a choreic character, as has been already discussed.

On purely clinical grounds, however, the evidence here adduced pleads clearly in favour of the hypothesis offered that athetosis and chorea are exteriorised via the corticospinal paths, and that behind their appearance is an afferent disorder of regulation, producing choreiform and athetoid characters in movement, ataxia or incoördination, and hypotonia. This afferent disorder or derangement of regulation is attributable to lesions situated on the cerebello-mesencephalo-thalamo-cortical path already described. As a consequence, "voluntary" movements via the corticospinal tracts exhibit characters corresponding to the functional defects; further, these tracts are, continuously or intermittently, usurped also by "spontaneous" movements of choreiform or athetoid character, movements in many ways closely resembling "voluntary" movements, over which the patient's inhibitory control remains desultory and incomplete. A persistent (or intermittent) stream of disordered cerebello-cerebral afferent stimuli keeps up the flow of "involuntary" movement; only in sleep are these excitations so damped down as to allow the movements to cease. During waking life, it may be for years, as we have seen, the stream flows to the cortex and the cortex ceaselessly responds.

Thus, in a definite sense, choreo-athetoid activity is the activity of cortical reflex arcs; the movements have cortical quality and yet they are "involuntary."

If the views here offered can be reasonably entertained, they lead to the conception of the possibility of "*involuntary*" *cortical motor activity*—a natural development of the hypothesis I have suggested. As far at least as chorea is concerned, the conception appears to me to have much to justify it, and little less in respect of athetosis. *The "spontaneous" activity of choreo-athetosis, thus conceived, is nought else than a succession of cortical "reflexes," high-grade movements largely comparable to those called "voluntary" except that the patient's "volition" neither initiates nor inhibits them.*

Further explanation, however, is requisite, in more than one respect.

(1) When I speak of cerebello-mesencephalo-thalamo-cortical dysfunction being an integral factor in the appearance of choreo-athetotic movements exteriorised via the pyramidal system, I do not limit the association to an anatomical link in the postcentral cortex. Thalamo-cortical fibre-systems are widespread, and a frontal radiation is just as definite as any to the postcentral gyrus, and no less important. For, on the efferent side, when I have been speaking in various preceding sections of the corticospinal system being usurped by movements of a "spontaneous" or "involuntary" kind, I do not wish it to be supposed that I regard the *anatomical* Betz-cell as the *physiological* terminus a quo of efferent motor activity. On the contrary, many lines of evidence are against such a supposition. From the excitable motor area (Betz-cell area) one does not obtain movements of so elaborate or intricate a pattern as are seen in everyday "volitional" action; the combinations of movement elicitable by the stimulating electrode are anatomical rather than physiological; the "march" of the movements in Jacksonian epilepsy is not paralleled in ordinary normal "volitional activity." For the complex movements of chorea, to take an example, we must postulate a motor centre higher in a physiological sense than that of the motor region *sensu strictiori*, and both clinical, pathological, and experimental evidence suggests that such a centre lies in front of the Rolandic area. Relatively short transcortical neural systems link the frontal to the Betz-cell area, and I imagine, consequently, that the afferent disorder of which I have spoken produces its effect by radiation from the thalamus on this postulated frontal motor centre, quite possibly from the parietal to the frontal cortex, and so on the (anatomical) origin of the corticospinal tracts.

(2) The inability of the choreic or athetotic patient to control adequately the abnormal activity of the cortical arcs of which I have spoken can only mean, translated into physiological terms, failure of transcortical inhibition from some unknown source. His "will-lessness" in respect of the abnormal motility from which he suffers can be nothing else, physiologically, than failure of one cortical element to inhibit another cortical element—a state of affairs the "extreme likelihood" of the occurrence of which is postulated by Sherrington for various fields of cortical action. Prosecution of this point would take me too far from my main thesis at present, but brief allusion to some aspects of the question may not be out of place. The objective study pursued in these lectures precludes, as I have shown, the likelihood of the corticospinal system (Betz-cell to muscle) being "voluntary" in any exclusive sense, though it is the *usual* path by which "voluntary" movements are

exteriorised. These must "start" at a still higher physiological level, as is apparent from the considerations advanced in the previous section. The "involuntary" movements of chorea are of a higher physiological type than those of Jacksonian epilepsy; therefore even the transcortical part of the whole "voluntary" motor efferent system is on occasion usurped by "involuntary" action. "Volition," therefore—always speaking physiologically—is driven back to some other transcortical source, remote enough from the Betz-cell, from whence its action on the whole motor path—say, fronto-rolandico-spinal—is, in the case of chorea, &c., very imperfect indeed; or, it is driven out by "involuntary" cortical activity. Consideration of the phenomena of chorea and of athetosis, of tonic innervation and of apraxia, and of cortical reflex arc activity in general, in my view, clearly supports this line of argument. "Volition," in short, seems to be little else than transcortical inhibition, a "voluntary movement" little else than a movement that is "allowed" transcortically, an "involuntary movement" (of this high class) little else than one that cannot be transcortically prevented.

It is of interest that the present objective studies point in the direction of these tentative conclusions, since quite other lines of research by other workers seem to indicate dissatisfaction with current conceptions. Lashley, for example, says "the conception of volitional activity is too vague to have any scientific value," and holds that the "volitional" or "automatic" character of the centrifugal neural impulses of the cortex can be defined "only in terms of their complexity of organisation and their relative importance in the total motor integration." Von Monakow, after declaring that the common views of pyramidal function must be essentially modified, says "it is probable that the pyramidal areas serve less for the execution of voluntary movements than for the inhibition of the kinetic *functions* of spinal coördination. Their function seems to be in the class of reflex activity." If lower centres are less under the directive than the inhibitory influence of higher centres, the same may well be true of some among the cortical centres themselves.

(8) Reverting finally, in this connexion, to the demonstrated disorder of reciprocal innervation characteristic of choreo-athetosis, we have to examine the question of the physiological level at which this phenomenon takes place. Reciprocal innervation is readily obtainable by stimulation of any particular single point on the motor cortex proper, but it is also produced by excitation of the internal capsule, the pyramids in the medulla, and at still lower levels. The action *of arrest* of one muscle and excitation of its opposite may certainly be elicited from the cortex, but, in Sherrington's own words, "the seat of inhibition in these reactions from the *motor* cortex lies probably at the place of confluence of conducting channels in a common path, likely enough at their confluence upon the 'final common path'"—in other words, at the spinal level. Clinically, too, it is likely, from a consideration of data that I cannot now elaborate, that the link between the muscular components of a given movement (protagonists, synergists, and antagonists) develops its activity at the spinal level, *but this* is not the whole question. We know quite well that reciprocal innervation is typical of the numerous spinal reflexes which can be elicited by stimulation of dorsal roots; this *has* been performed seriatim for cervical and lumbar roots by Sherrington and by Page May, and the widespread movement patterns thus *obtained* are systematised and largely invariable. Without reciprocal innervation such spinal reflexes would be impossible. Spinal coördination exists. But from the cortex itself, as we have seen, similar coördinated movements can be obtained, although they are limited in extent, as has already been remarked. Whether *precisely* the same coördinating mechanism in the cord is used both for spinal reflexes and for cortical impulses is undetermined; according *to* Graham Brown, "there is a finely differentiated mechanism in the motor cortex which does not set into action spinal centres in the same manner as do the in-going nerve-impulses carried by the sensory nerves of a limb, but is able in some way to pick out and set into action small portions, as it were, of the simple reflex movements." Be this as it may, *since reciprocal innervation is obtainable from the cortex, it can be deranged from the cortex.* It is in fact completely deranged in so-called tonic innervation, as I have previously demonstrated, and in these cases the lesions are situated in the frontal region and a transcortical effect is exercised on the pyramidal system. It is also entirely disorganised in choreo-athetosis, as has here been fully exemplified, and the argument which I have developed points definitely in the direction of a cortical arc being utilised for the hypermotility of these clinical states. While the ultimate stage probably is spinal, *the origin of the disorder in chorea and in athetosis is on the afferent side to the cortex or in transcortical neural systems from the afferent to the efferent side.*

I am not disinclined, from a study of my clinical cases, to suggest it is the cerebellar element, as I have already indicated, in the afferent cerebello-cerebral defect of regulation, that is responsible for the disarray of component units in a cortical movement, "involuntary" as the latter is (in the cases under consideration), and some experimental support for this view is forthcoming in the recent researches of Tilney and Pike. Although on clinical grounds I am not in accord with their general standpoint, their conclusion that the cerebellum appears to play a prominent rôle in maintaining the proper relation in the "synergic units" of the body has not a little to be said in its favour.

(To be concluded.)

Clinical and Laboratory Notes.

A CASE OF
ACUTE INTESTINAL OBSTRUCTION
DUE TO THE PRESENCE OF A DRAINAGE-TUBE LEFT IN THE PERITONEAL CAVITY.

BY R. LESTER WILLIAMS, M.B., B.CH. CAMB.,
F.R.C.S. ENG.,
LATE RESIDENT SURGICAL OFFICER, ROYAL INFIRMARY, SHEFFIELD.

THE following case of a foreign body lying unsuspected in the peritoneal cavity for 12½ years and causing no inconvenience is sufficiently unusual to justify its being placed on record.

R. H. J., male, aged 33, was admitted to the Sheffield Royal Infirmary on Jan. 13th last.

History.—On Jan. 11th at 4.45 P.M., while on his way to work, he commenced with slight abdominal pain. At 6 P.M. the pain was worse, and at 8 P.M. it became so severe that he had to leave work and return home. He vomited the same evening, and vomited repeatedly up to the time of admission. The bowels last acted on the morning of the 11th. On the 13th he was seen by his own doctor, who ordered two soap enemata at an interval of half an hour; the results of which were so poor that he ordered immediate removal of the patient to hospital with a diagnosis of intestinal obstruction. Previous history was as follows. In August, 1912, he had been operated upon for acute appendicitis, when an appendicular abscess was opened and drained with a rubber tube, but the appendix itself was not removed. After recovery from this operation he was sent home, and three weeks later was readmitted and the appendix removed. Since then he has remained perfectly well, and at work all the time. He has had no abdominal pain of any sort, and his bowels have acted daily without aperients.

Condition on Admission.—The patient was a healthy-looking man. Temp. 99.6 F°, pulse 80. A healthy healed pararectal appendicular scar was present. Abdomen distended and moved poorly with respiration. There was some slight general abdominal tenderness. Percussion yielded generalised tympanitic note; liver dullness normal. Rectal examination was very painful and could not be satisfactorily carried out. A diagnosis of acute intestinal obstruction due probably to adhesions or bands following the original operation for appendicitis was arrived at, and an immediate operation was performed.

Operation.—The abdomen was opened through a right lower paramedian incision. Coils of distended small intestine at once presented. The region of the old appendicectomy scar was first explored, but beyond some adhesions between the scar and the great omentum nothing abnormal was discovered. Passing down into the left side of the pelvis from the right iliac fossa a tubular structure not unlike a calcified internal iliac artery was felt. As there was no pulsation it was very cautiously dissected out from its sheath of peritoneum and fibrous tissue, and was found to be a piece of ordinary red rubber drainage-tube. On investigation of the pelvis it was discovered that the distal 4 cm. of the tube had passed through an aperture in the lowest part of the root of the pelvic mesocolon. Through this aperture had passed also about 3 feet of small intestine which had become strangulated. The strangulated gut was reduced without great difficulty, and on examination was found to be deeply congested but quite viable. The next problem was to close the opening in the pelvic mesocolon so as to prevent the possibility of a recurrence of the strangulation. The patient was placed in the Trendelenburg position and, with the aid of a headlight, a good view of the aperture in the pelvic mesocolon was obtained. The aperture admitted two fingers and running along its posterior margin were the inferior mesenteric artery and vein. The aperture was closed with some difficulty with two catgut sutures, during the introduction of which great care had to be taken to avoid damage to the inferior mesenteric vessels. The abdomen was closed in layers without drainage.

The patient made an excellent recovery and was discharged from hospital as cured 14 days after the operation. The drainage-tube measured 15 cm. in length and 1 cm. in diameter, and was in a perfect state of preservation. It contained four lateral holes (evidently for drainage), and the point where it passed through the hole in the pelvic mesocolon was marked by a well-defined constriction.

Comments.

The remarkable feature of this case is that, although the patient had this large drainage-tube in his abdominal cavity during the 12½ years that elapsed between the two original operations for appendicitis and the present operation for acute obstruction, he was nevertheless absolutely well, quite free from abdominal symptoms of any sort, and able to do full work. One would expect that the presence of a large drainage-tube amongst the intestines would have given rise to at least some abdominal symptoms due to the peristaltic action of the intestines pressing the tube downwards into the pelvis and through the base of the pelvic mesocolon. Had the tube not given rise to the attack of acute obstruction its presence could never have been suspected. The only really difficult part of the operation was the closure of the opening in the pelvic mesocolon which was so deep in the pelvis and which had the inferior mesenteric artery in such close relationship. The case illustrates the fact that although a large foreign body may lie for years unsuspected in the peritoneal cavity, it is always a source of potential danger to its host whose life it may place at any moment in the gravest jeopardy.

In conclusion, I wish to thank Mr. Ernest Finch, under whose care the patient was admitted, for his permission to publish this case.

VASO-NEUROSIS CAUSED BY TOXIC IDIOPATHY TO MILK IN A CHILD.

BY HECTOR M. WALKER, M.D. GLASG.

THE following case of vaso-neurosis in a child of 10½ months seems to be worthy of recording.

The baby, a male, weighed 21½ lb. He was 8¾ lb. when born. He had no illness beyond a rather troublesome dry eczema on the head, which came on when 2½ months old and lasted until about 6 months.

Condition on Examination.—When I saw him the mother complained that he had been sneezing a great deal for about a week and that lately he had come out in spots. On examination I found that he had an extensive urticaria on the front of the chest, abdomen, and legs. The right ear also was swollen to about twice its normal size, and was hot and red. The mucous membrane of the nose and throat was hyperæmic, but there was no catarrh. The swelling of the ear must have come on very quickly, since the parents had not noticed it, and it subsided about an hour after I left. The urticaria disappeared several hours later, but reappeared on the three following days, the attacks never lasting for long. Once the other ear became swollen. On the third day he developed diarrhœa, passing numerous small loose stools which contained abundant mucus. He had no sickness or temperature, but the appetite was poor. The mucus in the stools lasted for about three days.

The mother told me that the urticaria seemed to come on usually about an hour after he had taken any cow's milk. I did a sensitisation test by scarifying the skin on the arm and placing a drop of milk on it, and in about ten minutes there was an extremely marked reaction, a large circular red wheal being produced.

This case shows a general disturbance of the vascular innervation caused by sensitiveness to a foreign protein. By leaving cow's milk out of the diet there have been no further attacks of the urticaria, but the sneezing has persisted, although not so frequently as before. The association of urticaria, angino-neurotic œdema, vaso-motor rhinitis, and mucous colitis at the same time and in the same case is interesting. It seems probable in this case that the colitis was caused by the same influences which, acting on the skin, had caused the urticaria and, on the nasal mucous membrane, the rhinitis. There is no family history of asthma or vaso-neurosis.

Harrow.

A LOOSE BODY IN THE TUNICA VAGINALIS.

BY A. ERNEST SAWDAY, M.B., B.S. LOND.,

SURGEON TO THE DERBYSHIRE HOSPITAL FOR SICK CHILDREN.

I HAVE never met with any reference to a loose body in the tunica vaginalis, and the following note would appear to be of sufficient interest to place on record.

A boy of 8 was operated on in May, 1925, for a right undescended testicle, which was lying in the inguinal canal. On opening the tunica vaginalis a firm white mass, the size of a small pea, at once presented and slipped out. It was lying quite free, and there was no pedicle or adhesion whatever. The testicle, though maldeveloped, appeared otherwise anatomically normal. On microscopical examination of the loose body the section showed necrotic and amorphous fibrous tissue with areas of calcification.

What the origin of this body was it is difficult to say. Perhaps it was a detached cyst of the epididymis, or represented a cystic (? and tuberculous) degeneration of the hydatid of Morgagni or of the hydatid of the epididymis.

THE PRIZE-GIVING AT EPSOM COLLEGE.—Over 500 parents and friends were present on Saturday last at Epsom College, when the prizes were distributed by Lord Beauchamp. The following members of the Council were on the platform: Dr. Raymond Crawfurd, Dr. F. de Havilland Hall, Mr. Owen Lankester, Mr. Æneas Mackay, Mr. Samuel Osborn, Sir StClair Thomson, Sir Squire Sprigge, Dr. Harold Spitta, Sir John F. H. Broadbent, Surgeon Rear-Admiral Sir Percy Bassett-Smith, Mr. Douglas C. Bartley, Sir Ernest Goodhart, Dr. E. Climson Greenwood, Dr. Seymour Taylor, Sir Henry Dixon Kimber, Mr. T. Hollis Walker, K.C., Mr. A. Arthur Napper, and Sir William Hale-White. The headmaster, Mr. Arnold C. Powell, mentioned individual scholastic achievements by the boys, and said that in sports also the school was holding a good place. Lord Beauchamp, in presenting the prizes, said that the most important factor in education was not the prize, but the attempt to secure the prize. Dr. Raymond Crawfurd, Chairman of the Council, in proposing a vote of thanks to Lord Beauchamp, referred to the improvements in the equipment of the school effected during the past year, and those in immediate contemplation, and mentioned as two needs still existing a new infirmary, which would leave the old building available for the accommodation of more boys, and the levelling of the Lower School playing fields. The vote of thanks was carried by acclamation, after which tea was served on the lawns, where the band of the Second Battalion of the Queen's Own Royal West Kent Regiment played during the afternoon.

Medical Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

BIRMINGHAM, JULY 6TH–10TH.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held at the University of Birmingham on July 6th to 10th, under the presidency of Sir FREDERICK MOTT, F.R.S.

The PRESIDENT announced that the Council had nominated Lieut.-Colonel J. R. LORD, C.B.E., M.B., editor of the *Journal of Mental Science*, to be the next President.

The Sympathetic Endocrine System.

Dr. DAVID ORR (Prestwich Asylum) gave a lantern demonstration on the Sympathetic Endocrine System. Dr. Orr said that intellectual life was inseparable from emotion. Certain areas of the brain were associated with the registration of visceral impressions, and there was no impression in any part of the body which was not registered in the brain and which did not immediately react on certain organs. The central nervous system could not be spoken of as a system per se; it was intimately connected with the sympathetic system, and this latter with the ductless glands. As every impression reached the brain it was accompanied not only by its own specific sense, but by an emotional content, and it aroused certain things; it produced either a pleasant or an unpleasant sensation, as there was no such thing in the human mind as a negative impression. Dr. Orr proceeded to elaborate his thesis, and demonstrated what took place during a nervous upset. His main thesis was the intimate coöperative working of the whole mechanism and the need for treating patients from the physiological point of view.

The contribution was discussed by Dr. M. J. NOLAN, the PRESIDENT, Dr. W. F. MENZIES, Prof. G. M. ROBERTSON, and Dr. LORD.—Dr. ORR replied.

President's Address.

Sir FREDERICK MOTT then delivered his address. He said that no progress was possible in knowledge of mental disease until the spell of metaphysical speculation had been shaken off, as that carried with it the doctrine of mind as an invisible intangible spirit with an existence separate from the body. The functions of mind depended on the whole body and on the harmonious action of all its parts. In the apparently healthy brain there might be subtle biochemical and biophysical conditions which were dependent on inborn functional or bodily defects. The highest level of the brain was the first to undergo the deleterious effects of any form of intoxication. This highest level represented the psychic personality of the individual, and was the personal equation due to inborn tendencies and characters derived from racial and familial ancestry, near and remote. In mental disease there might be no discovered differences in the brain structure, even by powerful microscopy. There might perhaps be a vital germinal deficiency manifesting itself by an arrest of the development of many of the cortical neurons or a lack of durability. Or vascular conditions might be present which interfered with the nutrition of the rapidly developing neurons.

The speaker then proceeded to deal with the changes in the mental attitude coincident with the involutional period, adolescence, remarking that all psychic activities were subordinate to and dependent upon physiological processes. The functional correlation of mind and body was shown by the profound influence which the reproductive endocrine system exerted upon the evolution at puberty and on the sentiments which had their roots in the sex instinct. Steinach had shown that the substances of internal secretion had a selective action in storage in the central nervous system, and it was not sufficiently recognised that a climacteric might occur in men between 55 and 65 years of age, being associated in some of them—but not in all—with arterio-sclerosis. Some cases of involuntary melancholia had their origin in testicular regression and the concomitant endocrine gland changes. A study of relatives in a large series of cases in the London county asylums revealed three main facts in relation to the causation of mental disease: (1) The importance of a neuropathic and psychopathic heredity; (2) the special liability of the neuroses and psychoses to occur in adolescence; and (3) the influence of child-bearing and lactation in women, acting as an exciting cause.

The general conclusion he wished to enforce was that it was the duty of medico-psychologists to practise general medicine in its broadest sense, and ascertain whether there was present any body condition which could act either as a cause or a contributory factor in the production of the abnormal psychic state.

Psychological Implications of Encephalitis Lethargica.

Dr. G. A. AUDEN pointed out that the late sequelæ of this infection gave it a sinister importance which was intensified by the steep rise in the epidemic incidence which had marked the past year. Encephalitis opened up an entirely new outlook in psychiatry and neurology, which might bring us to a better understanding of the genesis of certain psychoses and neuroses. Confining his remarks to children between 5 and 15 years of age, he pointed out that the clinical picture presented by the disease was one of a generalised toxic condition, which fell with especial weight upon the nervous system; while the later manifestations, both psychic and somatic, formed a syndrome which gave all the features of a definite and distinct morbid entity. One of these was a characteristic failure of adjustment to the inhibitions and sanctions of the social order, especially in the direction of persistent thieving and lying. Other features, such as a reversal of the normal sleep rhythm, coupled with noisy excitability and perverse habits, seemed to bring the disease into definite relationship with certain types of mental disorder. A considerable number of children developed peculiar habits and tics. Some of these might be attributed in the first instance to increased suggestibility—e.g., the hawking and spitting might be the result of a salivation which had passed off. Occasionally cases showed iteration-compulsions. In some of the advanced cases of Parkinsonism there was a superficial resemblance to catatonia, but in these cases, as Economo had pointed out, the patients were apperceptively and intellectually intact; appreciating fully their relation to their environment; well orientated, and with undiminished critical judgment. The main characteristics were a combination of mental apathy with explosive irritability, a rapid onset of fatigue, and a marked drop in attention, with a heightened susceptibility to emotional stress. These might be correlated with an inhibition of volition and a failure of the exercise of self-criticism. In the opinion of the author the theory of the development of the nervous system put forward by Head and Rivers gave a key to the proper understanding of these character changes and volition defects. They appeared to be *regressions* due to a removal or suppression of the epicritic control over the protopathic instinctive tendencies. The child was essentially, in Lloyd Morgan's phrase, a "self of enjoyment," and it was only as he grew that the ceaseless stream of suggestions of social import raised in him a predisposition towards social conduct. He submitted the following table relating to 64 cases submitted to him for examination:—

	Cases.	Morbid changes (per cent.).
Reduced intelligence	29	45·3
Disturbed sleep rhythm	50	78·1
Marked irritability	45	71·3
Moral defects and character changes	21	32·8
Parkinsonism, bradykinesia, tremors	27	42·1
Perverted habits	29	45·3

With regard to treatment, if the theory set forth in the paper was correct, punishment could have little or no deterrent effect; indeed, it might have disastrous results by fixing an antisocial attitude through the creation of a conflict or an inferiority complex. Under the simple and regulated life of a special institution, differing from the Borstal or industrial school type, sufferers from encephalitis lethargica would re-acquire the necessary epicritic control to enable them to again take their places in ordinary life.

The President showed on the screen slides of the lesions he had found in cases of encephalitis lethargica, and briefly discussed the paper.—Dr. P. C. P. Cloake (Birmingham) agreed with Dr. Auden's conclusions. This disease could be put in the great group of toxic cases with mental symptoms, and he considered that the mind was disordered differently under the influence of different toxins. He discussed the pathology of the sleepy state at some length.—The paper was also discussed by Dr. G. H. Melson, Dr. S. J. Cole, Dr. Taylor, Dr. Lord, Dr. Helen Boyle, and Dr. A. M. McCutcheon.—Dr. Auden replied.

Chronic Infective Processes in Mental Disorder.

Dr. T. C. Graves (medical superintendent, Hollymoor Asylum) read a paper on the Incidence of Chronic Infective Processes in Association with Mental Disorder. He said that often the conditions found were beyond the possibility of cure, as they were slow, insidious, and hidden, and sometimes they had not given evidence of their presence. He narrated a number of cases in which slides of the dental condition were shown and the clinical notes read out. In some cases after extraction of teeth a root had been left, and the shutting in of infection had led to spread into the bone. Some people with undoubted septic foci seemed not to suffer disability from them, the explanation being that they were putting up an effective resistance. He also dealt with the questions of sinus infection, infection of ear, tongue, tonsils, and in the female the genital tract, and contended that these septic processes played a definite part in the causation and the duration of mental disorder.

The paper was discussed by the President, Dr. Cloake, Dr. Bedford Pierce, and Dr. J. G. Soutar. Dr. Graves replied.

Delinquency.

Dr. W. A. Potts read a contribution on this subject. He said he thought the time would come when all sexual offenders, those of a kind now sent to remand homes and those who had committed serious offences, would be referred for a special medical examination. The first duty was to see that the person concerned was not suffering from a physical or psychological handicap, the latter being divisible into inborn and environmental. The presence of a physical disability did not mean that there was not a psychical one also; but when a physical factor had been efficiently dealt with the psychological factor disappeared. Of this he quoted some convincing examples. In many cases of juvenile delinquency the problem was the parents. It had been said that 10 per cent. of delinquents were mentally defective, but Dr. Potts regarded that figure as much too high; it was nearer 2 per cent. Mental conflicts must be recognised and treated as such. Usually the delinquent was failing along more than one line. He had found that homosexual offenders had been retarded, especially on the emotional side, and they responded well to psychoanalysis.

There was a full discussion on this paper, the participants being Dr. R. W. Branthwaite, Dr. McCutcheon, Dr. Marr, Dr. Hamblin Smith, Dr. Lord, and Dr. Soutar, and Dr. Potts replied.

The Iodine Content of Thyroid Glands.

Dr. F. A. Pickworth read a paper with this title. It represented a further stage of the work done by Sir Frederick Mott and submitted to the Association at its meeting in Belfast last year, its aim being to correlate the iodine content with histological structure and the mental and bodily condition of the patient. Dr. Pickworth described and demonstrated in the asylum laboratory his new method of ascertaining the iodine content in glands. It consisted of the destruction of the organic matter by fusion with alkali and oxidation of the resulting iodide to iodate with permanganate solution, the excess of the latter being removed by means of animal charcoal. After filtering, potassium iodide was added, and the iodine titrated with thiosulphate. Arterio-sclerotic glands showed less iodine, and in fibrotic glands the iodine was very low indeed. A case of tuberculosis showed a lowered iodine content, but one of miliary tuberculosis showed iodine above the normal. A low quantity of iodine was also found in melancholia, mania, dementia præcox, and arterio-sclerosis, as well as in dementia. In the 39 cases of general paralysis of the insane there was a large range of variation in this respect. It became clear from this investigation of over 100 cases that the iodine content in the thyroid was very important in combating infections, though it probably was associated in this influence with the endocrine products.

Institutional Treatment of Mental Defectives.

Dr. A. M. McCutcheon read a paper on this subject, with special reference to occupational training. He said the objects of the treatment of mental defectives in institutions were four: (1) to correct their antisocial conduct; (2) to restore their self-respect and happiness; (3) to teach them the work for which they seemed most fitted, leading to discharge, if possible; and (4) by stopping the procreation of children and so to prevent the blight from being handed on. All these could best be achieved, he thought, by segregating them in institutions, preferably of the colony type. A keynote to success was adequate classification. There was a good discussion.

The Psychopathic Personality.

This subject was dealt with in a paper by Dr. Hamblin Smith (medical officer, Birmingham Prison). He said the cases dealt with formed a large but ill-defined group, the members of which found it impossible to make satisfactory social adjustments. They had a strong inferiority complex, and however well the physical treatment of them might be carried out, the psychical must not be neglected. These people had a "shut-in" personality, and the hope for the future lay in taking the psychological view of them.

At the dinner the Lord Mayor of Birmingham (Hon. Percival Bower), Dr. Nathan Raw, Miss Bartleet, J.P., Prof. Kauffmann, Prof. Sir John Robertson, and Alderman J. H. Lloyd, J.P., were among the guests, while there was a good attendance of prominent members of the Association. A visit was also paid to the Hollymoor Mental Hospital.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held on July 1st, the President, Sir David Wallace, being in the chair. Sir Edward Sharpey Schafer opened a discussion on

The Pituitary.

Dealing first with the anatomy of the gland, he demonstrated its four parts, and its embryological development. The pars nervosa was formed from the brain tissue, the other three parts, pars anterior, medialis, and tuberalis respectively, being of epithelial derivation. The pars tuberalis surrounded the tuber cinerium, thus remaining unremoved in the so-called complete removal of the gland. The main network of vessels for the blood-supply to the gland was in the pars tuberalis and pars anterior, and therefore these parts were the seat of the maximum glandular activity. Numerous sections of the gland were shown demonstrating colloid material and its escape into the cerebrospinal fluid in the third ventricle of the brain. The posterior lobe consisted of the pars intermedia and the pars nervosa, and the physiological action on the circulation of alcoholic extracts from this lobe were described. On first injection a marked rise was seen, but on a "repeat" dose a fall resulted. The injection from the posterior lobe of the gland caused a marked contraction of the intestine, bladder, and uterus. Milk secretion was notably stimulated, and this even occurred in mammals when an extract of fish's pituitary was used. In the urine a highly diuretic action was exhibited, but repeat doses might cause a lessened secretion. Entirely different actions of stimulation and inhibition were obtained from alcoholic extracts of the gland and of the residue after extraction. The physiological standardisation of tests was described. These were: oxytocic test, pressor test, melanophore test, urinary test, and mammary test. The anterior lobe was concerned with the growth and development in mammals, birds, and amphibia, and administration of the anterior lobe, whether orally or subcutaneously, caused excessive growth and gigantism, while removal of the gland produced the opposite effect. Prof. Schafer remarked on recent and useful work which had been performed in a study of the gland and its action.

Discussion.

Mr. H. M. TRAQUAIR spoke on the subject from the view-point of the ophthalmologist. Symptoms from enlargement of pituitary were of two sorts, glandular and local; the latter, due entirely to mechanical pressure, manifested themselves in visual changes. The effect of pressure was modified by the local anatomical formations, as the gland itself lay in the immediate vicinity of the optic chiasma. Enlargement caused diminution of the fields of vision. Slides were shown of the chiasma and numerous slides of visual fields demonstrating the progressive diminution in size, which occurred in a clockwise or anti-clockwise direction according to the eye affected.

Mr. NORMAN DOTT described various pathological conditions such as tumours, affecting the gland and the subsequent symptoms, which depended on whether the tumour enlarged in an upward direction or not. Destructive growths were accompanied by hypo-pituitarism, while growths of an adenomatous nature caused excessive secretion and corresponding symptoms of body growth and function in general. Diagnosis was greatly aided by radiograms defining the sella turcica and revealing calcification which occasionally took place as a degenerative change. Operative interference could be carried out from above through the cranial vault or from below through the nose.

Prof. JOHN FRASER referred to the marked increase in growth of tadpoles fed on pituitary tissue. Prof. EDWIN BRAMWELL spoke of a case of myopathy he was treating which presented all the features of hypopituitarism. Several cases of this type had been described in the literature and the association of the two conditions was too frequent to be regarded as a coincidence.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.

A MEETING of this Society was held at 122, Harley-street on July 6th, Dr. JAMES WATT, the President, in the chair.

Dr. PETER EDWARDS opened a discussion on

The Treatment of Pleurisy.

He regarded all pleural effusions as tuberculous unless negatived by the guinea-pig inoculation test; since pyopneumothorax was occasionally afebrile he advised the examination of all effusions. He considered that efficient strapping of the chest diminished the incidence of effusions. When an effusion occurred in the less active side of a bilateral case he recommended partial aspiration and temporary gas replacement, employing a small-bore needle after previous softening, if necessary, with Sir Henry Gauvain's "1.2.3" solution; complete aspiration resulted in a rapid recurrence of the fluid. Dr. Edwards emphasised the importance of rigid asepsis in cases of artificial pneumothorax, and said that he was satisfied that neither the bore of the needle, the degree of pressure, the type of gas, nor its temperature had any influence on the development of effusions. The type of fluid was important on account of the production of adhesions, and it should be removed when it masked the full view of the collapsed lung, in spite of Dumarest's faith in the utility of benign effusions, because (1) the pleura still thickened after gas replacement; (2) all Dr. Edwards's cases of perforation had occurred in hydropneumothorax cases; (3) he considered fluid a very inefficient splint. If the effusions were left there should be a daily cytological examination and screening both in upright and recumbent positions. Other indications for gas replacement were: (1) When the mediastinum tended to move towards the side of the collapsed lung—here a high positive pressure should be left; and (2) when the fluid was fibrinous. In cases where it was purulent 10 c.cm. of a 0·2 per cent. solution of methylene-blue might be injected into it; this did not stop fluid formation but it mitigated the malignancy. Occasionally he had irrigated with saline, leaving a small quantity of methylene blue solution in the cavity. He quoted Water's successful employment of Churchman's joint-irrigation apparatus in aspirating the fluid, irrigating first with saline, then with a 1 in 1000 gentian-violet solution until the return flow is clear, and finally leaving a small quantity of the latter in the cavity. He had abandoned as quite ineffective the method of auto-serotherapy. For an effusion in the contra-lateral side of an artificial pneumothorax case he lowered the pressure and so made the pneumothorax partial, this being definitely advantageous, and then he aspirated.

Dr. ELEANOR SOLTAU drew attention to the fact that adherent pleura occasionally occurred unexpectedly in early cases without giving rise to any symptoms. One of the most useful indications was the sucking in of the intercostal spaces on inspiration, especially noticeable when the patient was in the usual position for induction of artificial pneumothorax. Dry pleurisy was not a hindrance and the subsequent limitation of movement, due to formation of adhesions, was probably beneficial.

Dr. A. R. SNOWDEN, in dealing with chronic and purulent effusions, excluded empyemata and limited himself to purulent effusions subsequent to a pneumothorax, spontaneous or artificial, or arising de novo from acute effusions. Removal or reduction of such was not advisable as a routine measure, but was indicated in the following circumstances: (1) If any interference with the circulation or heart's action were present. (2) If associated with indigestion, usually resultant from toxic and mechanical causes. (3) When the liquid filled two-thirds of the actual pleural cavity owing to the risk of jellification. (4) If active pus formation were in progress. Apart from these drawbacks, he considered an effusion to have a neutral if not a beneficial action as a splint and as a restraining influence on an irritable diaphragm, though an inert gas replacement resulted in less thickening and also allowed of more accurate X ray screening of the collapsed lung. He divided cases in two classes: (1) Those to be left alone, or have their fluid level maintained steady by gas replacement, keeping the final inspiratory and expiratory pressures constant. (2) Those to be eliminated by repeated gas replacements, with diminishing gas pressures. If the effusion be chronic the replacement should be done by degrees with intervals of from 8 to 14 days. He deprecated the frequent use of high pressures. Nitrogen, oxygen, and very dilute chlorine were the gases employed, but oxygen was found very irritant. In his experience purulent effusions were usually sterile and tended to clear up more quickly than simple ones. He had seen afebrile purulent effusions become non-purulent under the influence of ultra-violet radiation. Small doses of sunlight had also been beneficial. He had discontinued lavage as it caused thickening and occasionally sinus formation.

Dr. COLIN MILNE first discussed the differential diagnosis and then reviewed in detail the elements of local and general treatment of dry pleurisy. He pointed out that the induction of artificial pneumothorax for pleuritic pain was of limited use since it often occurred on the less affected side in bilateral cases. He quoted Fishberg's statement that 40 per cent. of dry pleurisies were tuberculous, in view of which he doubted the wisdom of alarming the patient unduly by diagnosing him as tuberculous in the absence of other physical signs. For the neurotic type of patient with pleuritic pain he resorted to the more drastic counter-irritants. In other patients he regarded pain as an indication of an exacerbation of the disease and ordered increased rest.

Discussion.

Dr. H. DE CARLE WOODCOCK reported that he had not had satisfactory results with gas replacement or injection of antiseptics in the more virulent forms of purulent effusions, but in simple effusions replacement was worth doing. He quoted Mr. Morriston Davies's recommendation to remove the gas if fluid returned so rapidly as to cause distress.

Dr. F. R. G. HEAF strongly recommended the inunction of iodex followed by exposure to radiant heat. He disagreed with Dr. Edwards's view that fluid was not an efficient splint.

Dr. G. M. MAYBERRY also advocated the use of iodex, but found methyl salicylate a useful addition.

Dr. ESTHER CARLING had found expectant treatment the best, and Dr. W. C. FOWLER reported favourably of his experiences with the use of radiant heat.

Dr. C. D. S. AGASSIZ replied to Dr. J. D. LEIGH's inquiry as to the occurrence of effusion in children, that it was very rare, and those few that did develop were probably not tuberculous.

A communication from Dr. VERE PEARSON was read in which he considered that oxygen replacement of an effusion following artificial pneumothorax was indicated in these circumstances: (1) If the chest were three-quarters full. (2) If the chest were one-third or more full, but associated for more than three and a half weeks with toxæmic symptoms. (3) If X rays showed that there was a danger of the lung expanding and becoming adherent. (4) If the fluid, though small in amount, was causing serious discomfort to the patient; this might occur in a convalescent patient on resuming a more active life. (5) In the rare cases of secondary infection of the fluid. In the case of spontaneous pneumothorax roughly the same rules for withdrawal of fluid held good, but the situation was complicated by the presence of an opening in the lung and frequently by secondary infection. Treatment must aim at dealing with these difficulties as well as at keeping the lung compressed long enough to obtain healing of the disease. Skilful adjustment of pressure by gas or fluid-withdrawal aided in healing the hole, while suction drainage and washing out the pleura often diminished the bad effects of sepsis. Open drainage was seldom called for, as it was very difficult to secure closure of the external sinus, and with this type of patient the hole in the lung also tended to remain unhealed. Thoracoplasty was sometimes of use in these cases provided the patient's general condition was good.

THE Nineteenth Voyage d'Études Médicales, which had been announced for September next, will not take place, difficulties having arisen at the last moment with respect to the facilities offered.

PROCEEDINGS OF THE
ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 182.)

EVIDENCE OF OPTICIANS' ASSOCIATIONS.

Institute of Ophthalmic Opticians.

(App. LX. and Q. 17483–17617.)

EVIDENCE was given on behalf of this Institute by Mr. Owen Aves, Mr. F. T. Gregg, and Mr. J. Forrest. Its members number over 1300 qualified persons; they are limited to those who hold (1) the qualification by examination for sight-testing of the Worshipful Company of Spectacle Makers; (2) the qualifications of the British Optical Association; or (3) the qualifications of the State Boards of Registration for Qualified Opticians in those parts of the British Empire which have already adopted legislation for the regulation of sight-testing opticians.

The general argument of the statement put in is to the effect that in the majority of cases the necessary treatment is sight-testing and the provision of optical appliances, and that this can quite safely be given by the qualified optician without the intervention of the medical practitioner or the ophthalmic specialist.

(Q. 17491.) The overwhelming majority of cases, we would say at least 95 per cent., require solely refractive treatment. . . . Such cases call for no intervention whatever of either the medical practitioner or the ophthalmic specialist, and . . . the qualified ophthalmic optician is the very best person to determine whether any such additional intervention or treatment is necessary.

The witnesses objected to the requirement which they understood to be imposed by the Ministry of Health that an application for ophthalmic benefit must only be considered by an approved society if it is accompanied by the written recommendation of a qualified medical practitioner.

With regard to the training of the qualified optician they made the following statement, and said that the Institute and other optical organisations have repeatedly requested the Ministry of Health to make thorough and searching inquiry into the facilities for training, and the methods of conducting the examinations for optical qualifications for diplomas in refraction.

(App. LX. 13.) The training of the qualified optician is not only intensive with respect to the theory and practice of refraction, but is also extensive concerning matters cognate to and arising out of such practice. Beginning with a basis of mathematics the optical student proceeds to the specific study of geometric optics and the properties of lenses. His further studies include ocular anatomy and physiological optics, on which foundation he is then taught the principles of sight-testing and the correction of refractive errors. Lastly he is taught to detect abnormal cases which require medical or surgical attention, in order that he may fulfil his ethical obligation to the public to pass on for medical advice those cases which require other than optical treatment.

The examinations of the British Optical Association and of the Worshipful Company of Spectacle Makers are, it was stated, conducted by eminent ophthalmic surgeons, refractionists, and physicists, and are admittedly searching in character and comprehensive in scope.

While the members of the Institute work in close coöperation with medical practitioners generally, and with many ophthalmic surgeons, they suggest that the large majority of medical insurance practitioners do not profess to know anything of refraction, and, as fully occupied public servants, are only too glad to avail themselves of the services of the qualified optician.

The witnesses contended that while clinical training in observation is certainly desirable and, in fact, given to the optical student, medical training in a therapeutic sense is not necessary. The following passage[1] was quoted in support of the view that thorough optical training is impossible to the average medical student with the present overloaded medical curriculum.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

> (Q. 17408.) "The examination of the eye is conducted on principles so different from those employed in ordinary surgical and medical diagnosis that the help to be gained from the latter is practically valueless; the practitioner must, therefore, be prepared at first to approach the subject with his mind wholly detached from medicine and surgery."

The number of qualified opticians is sufficient to give optical benefit to the whole insured population.

With regard to the detection of disease, the sole duty of the optician where he finds evidence of disease is to send the case to a doctor, and the witnesses maintained that the fact that the refractionist is so competent to detect diseases of the back of the eye has led to the discovery of those diseases.

> (Q. 17510.) The patient is under the impression that his case is one merely of refraction, and . . . he visits the sight-testing optician in the hope that his case may be merely one of defective sight. The optician at once sees the cause of the trouble or of the symptoms. . . . If an ocular disease be present it is equally recognisable by the ophthalmic *optician as by the oculist.*

Amongst the recommendations of the Institute were the following: (1) That optical benefit should be extended to every insured person, preferably on a cash basis; and (2) that steps should be taken to set up a departmental committee to consider (*a*) the need of a national service of refractionists which would work under the National Health Insurance Act; (*b*) the definition of a standard of qualification for National Health refractionists.

Joint Council of Qualified Opticians.

(App. LXI. and Q. 17618–17704.)

This Council maintains a register of opticians who have passed the recognised examination, and administers a scheme of optical treatment in coöperation with approved societies. Mr. J. H. Sutcliffe, Mr. F. W. Bateman, and Dr. Margaret Dobson were the witnesses. This evidence to some extent covered similar ground to that given by the Institute of Ophthalmic Opticians. The register which is kept has no statutory force, but serves for purposes of disciplinary control. It was drawn up chiefly for the guidance of those approved societies who wanted to make use of the Joint Council's service.

With regard to the proportion of cases which come to the optician for refractive error, and which ultimately require ophthalmic treatment, one of the witnesses said:—

> (Q. 17624.) Out of the 35,000 cases last year only 303 were referred for medical treatment. This is less than 1 per cent. On the other hand, I can imagine that the cases presenting themselves at the out-patients' department of an eye hospital or a clinic would, perhaps, include fully 50 per cent. of diseased cases, the reason being that such cases would not present themselves if they were not eye diseases, as nearly all eye diseases are generally obvious to the patients themselves, and therefore do not go to the optician.

Asked to develop the argument for differentiating between the eye and other organs of the body as regards persons entitled to render remedial treatment, the witnesses said:—

> (Q. 17628.) With the eye it is simply a case of interposing a certain lens or refractive medium in the air between the eye and the object viewed. The skill of the optician is concentrated upon the determination of the position and the curvature of the lens. He does not add to or take away from, alter the shape or constitution of the eye any more than a cinema lantern operator in focusing the lantern has any effect upon the audience, other than that of making the pictures more or less comfortable as well as clear. Discomfort arising from an incorrect pair of glasses will be greater than any damage that could be done, as the patient can by discarding the glasses voluntarily return to his original state.

In view of this evidence, the question was asked why the witnesses objected so strongly to the unqualified optician. They said, in reply, that the unqualified man could do great harm, because he has not the training to detect an abnormal fundus. The harm that he may do is in failing to send cases to the ophthalmic surgeon rather than in supplying wrong spectacles.

These witnesses protested, as did the previous witnesses, against the action of the Ministry of Health in requiring an insured person to have a recommendation from a medical practitioner if he needed spectacles, and also against the intention of the British Medical Association to charge any doctors recommending patients to a sight-testing optician with infamous or covering conduct. They readily agreed that the ophthalmic surgeon is a higher authority on the diseases of the eye than the qualified optician, but they said that in turn the qualified optician knew more about the eye than the ordinary general practitioner. The implication in the statements of doctors that opticians lacked the necessary skill could only be due to the fact that those making them had not taken the trouble to ascertain how the qualified optician has been trained.

British Optical Association.

(App. LXII. and Q. 17705–17771.)

This Association is a training and examining body, and confined its evidence to amplifying what had been said by previous witnesses in regard to the schemes of training and examination. Evidence was given by Mr. W. B. Barker, Dr. J. McHoul, and Dr. J. L. Meynell.

During the last 30 years the Association has examined 3061 candidates, and has issued about 250 honours certificates and about 1050 fellowship certificates. The standard required of successful candidates is a high one, and on an average not more than 40 per cent. of the candidates qualify. The Board of Examiners appointed by the Council consists of scientific men, several of whom are ophthalmic surgeons. Its rules and practice are modelled upon those which prevail in the medical and dental professions. The treatment of defective eyes otherwise than by glasses is strongly discouraged by the Association, and the prohibition is enforced where necessary (like other disciplinary measures) by the withdrawal of the Association's certificate of qualification.

With regard to their high standard, the witnesses quoted from a lecture delivered in 1920 by Mr. W. S. Todd, an examiner of the Association, who was chairman of the Examining Boards of different States in America. He said:—

> (Q. 17708.) I think it is extraordinarily important that the British Optical Association should be recognised. I have had the privilege of examining for the British Optical Association, and one thing that has surprised me is the very high standard of knowledge. I can speak as a member of the medical profession very much interested in eye work. When I qualified at London University I would not have known the answers to the questions that I had to ask the students at the British Optical Association's examinations.

No difficulty is experienced in securing medical men to act as examiners; on the contrary, the Association have to refuse applications from ophthalmic surgeons because their quota is full. The Association courted the fullest inquiry into their procedure and constitution.

With regard to the United States, the training is conducted at certain recognised State schools and universities in the same manner as at similar colleges of technology in this country. The State Boards of Examiners insist on attendance at those schools before they allow a candidate to sit for the examination; and in certain States the examination of the British Optical Association is regarded as part exemption from those examinations.

For the requirements of an insurance optical service, the witnesses pointed out that as against 500 ophthalmic surgeons willing to undertake the work there were 2500 duly qualified opticians.

---

[1] The quotation is from Ophthalmology in General Practice, by Dr. M. L. Hepburn, surgeon to the Royal London Eye Hospital.

In answer to a question similar to that put to previous witnesses as to the case for differentiating between the eye and other organs as regards persons entitled to render remedial treatment, the witnesses quoted Mr. Bishop Harman in support of the view that the eye is the only organ of the body where by direct observation its internal condition can be fully examined.

> (Q. 17723.) As opticians we claim to be physicists, and to supply a proper physical appliance for the correction of a physical error. In our studies we aim, in addition to that, not at a knowledge of pathology at all . . . but a very high knowledge of anatomy and physiology, so extensive that we can immediately detect any departure from normal appearance or function and immediately refer any clients so affected to the trained pathologist. . . The use of the two words "remedial" and "treatment" in the question are misleading. The qualified optician neither prescribes remedies nor does he undertake anything but purely optical treatment.

They also said that the law, as interpreted by the Lord Chief Justice in the case of Markham *v.* Thomas, imposed upon the optician the onus of detecting pathological conditions. Ever since the decision in that particular case the optician has been very anxious indeed, in his own interests, to make sure that he had the skill and ability to detect those conditions.

ROYAL SANITARY INSTITUTE:

CONGRESS AT EDINBURGH.

JULY 20TH–25TH.

THE Congress began on July 20th with a luncheon in the Students' Union, where Mr. Ewan F. Macpherson (Scottish Board of Health) remarked on the advances in hygiene which marked the progress of the Institute. The formal opening took place in the M'Ewan Hall, the chair being at first occupied by the Marquess of Aberdeen and Temair (a Vice-President of the Institute), who read a letter from the Duke of York regretting his absence. He then introduced the President of the Congress, Sir John Gilmour (Secretary for Scotland), who recounted how many-sided were the health problems of the Government and how well they had been met. He observed that Scotland was particularly easy to manage hygienically as she had always plenty of good water near her great aggregations of population; on the other hand, it was difficult to bring nurses in touch with all patients in the scattered isles. In each of its populous centres there was a university from which knowledge of hygiene was easily spread. Prof. Lorrain Smith was much struck with the personal care people were getting from health officials; the profession was coming again into personal touch with the community on the protective side too, where they seemed for a time to have lost that touch. Alderman W. Phene Neal (London City Corporation) hoped the Congress would be specially successful, as an encouragement to London, where next year's congress was to be held. Resolutions at conferences did do good. He had voted many times asking for municipal slaughter-houses, and now the last private slaughter-houses were to be closed in London. He wondered if people in general realised that 16 per cent. only of our meat was home-grown, only 14 per cent. in London, where only one loaf in ten was of English wheat.

TUESDAY, JULY 21ST.

The *Section of Sanitary Science* was opened by Sir George Newman, the President, whose speech was reported in our last issue. The other papers were on immunity and infectious disease, and great interest was taken in the Edinburgh attack on diphtheria by the Schick test and toxin-antitoxin injection, voluntary as far as the parents were concerned, but few objected; 16 cases of diphtheria had since occurred in children, shown to be positive, but not protected. Immunisation is giving very satisfactory results.

In the *Section of Industrial Hygiene* Captain W. E. Elliot, M.P. (Under-Secretary of Health for Scotland), who presided, said the capital of a nation was mainly in the bones, muscles, and grey matter of its citizens. Without health no other wealth has value. But if the power of man, as in machines, increases without improvement of his grey matter he will perish like the huge but small-brained diplodocus and its congeners. There was great loss of work by sickness; men lost more than women from diseases of the eye and apoplexy, women more than men from diseases of veins and anæmia. Regular repetitive work is monotonous—may not the present passion for betting be the outcome of monotony? When he noted the great advances in health made in recent years, the work of physicians, he was proud that he too had been a physician. He then had to leave, when his place was taken by Lieut.-Colonel F. E. Fremantle, M.P. Sir Thomas Oliver read a paper on Dusty Occupations and their Effect on the Lungs. Coal-dust, he said, did no harm; it was the stony, gritty particles that damaged the lung, intensified if bronchial catarrh or tubercle should supervene. Arsenic miners at Schneeberg in Saxony had lately begun to suffer from cancer of the lung (arsenic miners in Cornwall do not), ascribed by Ludwig to radium emanations associated with their dusty operations. Alderman Halsted (Dursley) hoped people would not mind paying a little extra for their coal in order to increase the precautions against dust in mines. Sir Thomas Oliver, in replying, mentioned that the dustiest operation he knew was making millstones in France; the men became very thirsty, drank freely, and at 40 were old men.

Mr. Sydney Tatchell, F.R.I.B.A., read a paper on Hygiene and Industry, stressing the importance of attention to the conditions of offices and to the protection of clerks, and telling how he had remodelled a City office, particularly by removing partitions and throwing large rooms open. Councillor Julyan (Poole) said sanitary authorities should take the lead in giving their clerks good working conditions. The difficulty is clerks are not protected by the Factory Acts. Dr. C. S. Thomson (M.O.H., Deptford) said he had been asked to lecture on health at Deptford, which he agreed to do if not less than 500 came to hear, and on these terms he had given several lectures. Dr. W. J. Howarth (M.O.H., City of London) said London offices were extending into basements, very dark and airless, forbidden as dwellings. He thought the present maximum height might be reckoned to the cornice, and the storeys in the roof counted extra. One difficulty was that the people in the dark offices did not themselves complain. Dr. J. J. Buchan (M.O.H., Bradford) said education in hygiene for youths was the proper way of advance. Health visitors told him that domestic servants made the best mothers. It was clear that the others must be trained. Mr. Alexander Johnston, J.P. (North British Rubber Company), read a valuable paper on Industrial Welfare, showing how welfare work had become an integral part of management. It increased output, and produced friendliness and esprit de corps. Works councils helped to prevent accidents, and by mutual understanding led to better training.

On Tuesday evening, in the Synod Hall, Sir W. Leslie Mackenzie (Scottish Board of Health) gave a lecture on the *Problem of Psycho-physical Fitness*, which, as Sir George Newman, who presided, said, was, in other words, how to raise a fit imperial race. When, asked Sir Leslie Mackenzie, was a man fit? Fitness is a pure abstraction, but in the war a direct answer had to be given when it was found that of nine men three were fit for any work, two were on a definitely infirm plane, three could do very little, and one was a chronic invalid. We could increase the number of the fit by staying the progress of disease. Tubercle was decreasing, typhoid had been nearly banished. Rheumatism still took a great toll, for nearly one-sixth of industrial debility was due to rheumatic diseases. We should concentrate on prenatal work, infant welfare, and the health of the school child. We might, if we chose, in a generation get rid of diphtheria and scarlet fever. No one need take small-pox unless he wished. So much for physical fitness. Great

advances in psychology had been recently made, and we could work better to secure mental fitness. Besides insanity we had to guard against the obsessions, unreasoning fears, bad tempers. Insanity was itself a disorder of conduct. The child lived in a world of its own, and it was the duty of the teacher to see that it learned without a jolt to adjust itself to life with others. These shocks caused mental conflict. The feeble-minded must be segregated. Mental and physical health were parts of the same problem, the man who neglected either would fail in both. In seconding a vote of thanks to the lecturer, Dr. C. J. Fernandes (Bombay) expressed surprise that England, which had taught India to escape small-pox by vaccination, seemed itself to have lost faith in the specific. Dr. Andrew Balfour moved a vote of thanks to Sir George Newman, who remarked on the benefit of the Congress in bringing together on the same plane the servant, the medical officer of health, and his masters, the members of sanitary authorities.

WEDNESDAY, JULY 22ND.

The *Section of Personal and Domestic Hygiene* was addressed by the Marchioness of Aberdeen and Temair, (the President), who said the great difficulty they still had to face was the apathy of those whom they hoped to benefit. Certainly they were dulled by the dreadful housing conditions against which many mothers were striving heroically. The Royal Sanitary Institute was doing splendid work by increasing popular knowledge. She had had experience of the interest evoked in Ireland by travelling health exhibitions with good demonstrators. Such exhibitions proved a profitable investment for local authorities which wanted support from their constituencies. In practice it was best to start with an attack on tuberculosis, and later to show the benefits of child welfare and the values of foods. She cited the example of the junior Red Cross societies, centred in Paris, which induced children to learn health as a game, thereby speeding up the parents. She had even heard of children in Dublin eager to be the first treated by the dentist. Such was the change wrought. The Playground Association of America for old and young was doing great work. A street with little traffic was closed in the evening, a paid organiser set the children playing. After a few nights the parents began to join in. They got the whole community together to tell stories, to perform plays in the children's summer and winter holidays. This was occurring in 680 cities of the United States, with less crime and less juvenile delinquency as the result.

Dr. Joan Rose (Edinburgh) read a paper on rickets, which elicited from the members a hope that proprietary starchy foods might be forbidden by law, and an intention to combat rickets by better feeding of the expectant mother.

Dr. R. A. Lyster (M.O.H., Hants), in his presidential address to the *Medical Officers of Health*, emphasised the difficulties of dealing with mental defectives, particularly if they married, and said that sterilisation had been recommended by a committee in New Zealand. The greatest hindrance to preventive medicine to-day was the inadequate instruction of young doctors in public health. A course of State medicine was needed which would harmonise the views of the profession with the needs of those who would be working under the National Health Insurance Act. Dr. A. K. Chalmers (M.O.H., Glasgow) said that the tenement system of housing on many floors was characteristic of Scotland, the cottage system of England. But each was now developing along the lines of the other, England building blocks of flats, Scotland providing four cottages in one block, giving each house a separate entrance. They could not dissociate the higher incidence of infectious and respiratory disease in Scotland over that of Wales and England from its system of housing in tenements.

In speaking to a crowded meeting of the *Representatives of Sanitary Authorities* in the City Chambers, the Lord Provost in the chair, Lieut.-Colonel F. E. Fremantle, M.P., claimed that the Government had been systematically working out a great scheme of health administration. But there was much overlapping in the departments of Government; recruiting, pensions, housing concerned various departments, and each had to decide its own policy. There should be a unified health service under the Prime Minister, like the Committee of National Defence, advisory, not executive. He proposed, and the meeting unanimously passed, a resolution pressing the Government to set up the promised Committee of Civil Research, with special emphasis on its health activities, to be applied by the various departments of Government.

Councillor W. B. Smith (Glasgow) told of the plant set up in Glasgow for providing smokeless fuel which would, he hoped, prove a commercial success, and might in addition solve the smoke problem.

In the evening the Lord Provost, magistrates, and council held a reception in the fine rooms of the College of Art, the guests being entertained with well-sung Scottish and other songs and the music of the "pipes."

THURSDAY, JULY 23RD.

At the *Conference of Port Sanitary Authorities*, Councillor W. J. Harvey, chairman of the Edinburgh Public Health Committee, the *President*, said that the work of these authorities was so good that attention was rarely directed to it. But it was very important as being the "coastguard of health," and that in its inspection of food from abroad it should exclude all tuberculous meat. The conditions of sailors in ships with 120 cubic feet as the statutory minimum were intolerable. Dr. R. M. Picken (M.O.H., Cardiff) presented a paper on destroying vermin on vessels. Sulphur dioxide can kill both rats and fleas. Hydrocyanic acid is quicker and, as it kills the flea on the rat's body, is useful for identification. The general opinion of speakers seemed to be that hydrocyanic acid, though effective, was dangerous, while sulphur (1¼ lb. for every 1000 cubic feet in well-sealed ships) if properly used was as effective. Dr. W. M. Willoughby (M.O.H., Port of London) contributed a most interesting paper on the suggestions of one James Augier, arraigned as a quack, to get rid of plague in London in 1665 by the burning of sulphur. Dr. Mitsuzo Tsurumi, of Japan, read papers on Pneumonic Plague, which had again arisen among the tarbagans. Fleet Surgeon W. E. Home submitted a standard death-rate for merchant seamen, and, seconded by Alderman F. Askew (chairman, Hull and Goole Port Sanitary Committee), moved a resolution asking the Council again to represent to the Government that better statistics were needed of the deaths of merchant seamen, who should be brought, for purposes of health considerations, under the care of the Ministry of Health.

The *Popular Lecture* was given by Dr. C. Porter (M.O.H., Marylebone), born and brought up in Edinburgh, who declared that higher developments of health in the future were to be attained by the constant interest of the citizen in his own health, which he will keep up by occasional visits to a doctor for investigation.

FRIDAY, JULY 24TH.

At the *Closing Meeting* it was stated that the attendance had been 1640, a record number. There were 875 delegates sent by 500 authorities.

The *Official Dinner* was held on Friday evening in the North British Station Hotel, the Chairman of the Council, Sir Henry Tanner, being in the chair. Prof. Bostock Hill, proposing the Lord Provost, magistrates, and Council of the City, the most beautiful in the world, spoke of the success of the Exhibition which had been particularly noticeable for its demonstration of women's work in hygiene and of the Scottish apprentices in plumbing. The Lord Provost, Sir W. L. Sleigh, thanked the Congress for the encourage-

In answer to a question similar to that put to previous witnesses as to the case for differentiating between the eye and other organs as regards persons entitled to render remedial treatment, the witnesses quoted Mr. Bishop Harman in support of the view that the eye is the only organ of the body where by direct observation its internal condition can be fully examined.

> (Q. 17723.) As opticians we claim to be physicists, and to supply a proper physical appliance for the correction of a physical error. In our studies we aim, in addition to that, not at a knowledge of pathology at all . . . but a very high knowledge of anatomy and physiology, so extensive that we can immediately detect any departure from normal appearance or function and immediately refer any clients so affected to the trained pathologist. . . The use of the two words "remedial" and "treatment" in the question are misleading. The qualified optician neither prescribes remedies nor does he undertake anything but purely optical treatment.

They also said that the law, as interpreted by the Lord Chief Justice in the case of Markham *v.* Thomas, imposed upon the optician the onus of detecting pathological conditions. Ever since the decision in that particular case the optician has been very anxious indeed, in his own interests, to make sure that he had the skill and ability to detect those conditions.

ROYAL SANITARY INSTITUTE:

CONGRESS AT EDINBURGH.

JULY 20TH–25TH.

THE Congress began on July 20th with a luncheon in the Students' Union, where Mr. Ewan F. Macpherson (Scottish Board of Health) remarked on the advances in hygiene which marked the progress of the Institute. The formal opening took place in the M'Ewan Hall, the chair being at first occupied by the Marquess of Aberdeen and Temair (a Vice-President of the Institute), who read a letter from the Duke of York regretting his absence. He then introduced the President of the Congress, Sir John Gilmour (Secretary for Scotland), who recounted how many-sided were the health problems of the Government and how well they had been met. He observed that Scotland was particularly easy to manage hygienically as she had always plenty of good water near her great aggregations of population; on the other hand, it was difficult to bring nurses in touch with all patients in the scattered isles. In each of its populous centres there was a university from which knowledge of hygiene was easily spread. Prof. Lorrain Smith was much struck with the personal care people were getting from health officials; the profession was coming again into personal touch with the community on the protective side too, where they seemed for a time to have lost that touch. Alderman W. Phene Neal (London City Corporation) hoped the Congress would be specially successful, as an encouragement to London, where next year's congress was to be held. Resolutions at conferences did do good. He had voted many times asking for municipal slaughter-houses, and now the last private slaughter-houses were to be closed in London. He wondered if people in general realised that 10 per cent. only of our meat was home-grown, only 14 per cent. in London, where only one loaf in ten was of English wheat.

TUESDAY, JULY 21ST.

The *Section of Sanitary Science* was opened by Sir George Newman, the President, whose speech was reported in our last issue. The other papers were on immunity and infectious disease, and great interest was taken in the Edinburgh attack on diphtheria by the Schick test and toxin-antitoxin injection, voluntary as far as the parents were concerned, but few objected; 16 cases of diphtheria had since occurred in children, shown to be positive, but not protected. Immunisation is giving very satisfactory results.

In the *Section of Industrial Hygiene* Captain W. E. Elliot, M.P. (Under-Secretary of Health for Scotland), who presided, said the capital of a nation was mainly in the bones, muscles, and grey matter of its citizens. Without health no other wealth has value. But if the power of man, as in machines, increases without improvement of his grey matter he will perish like the huge but small-brained diplodocus and its congeners. There was great loss of work by sickness; men lost more than women from diseases of the eye and apoplexy, women more than men from diseases of veins and anæmia. Regular repetitive work is monotonous—may not the present passion for betting be the outcome of monotony? When he noted the great advances in health made in recent years, the work of physicians, he was proud that he too had been a physician. He then had to leave, when his place was taken by Lieut.-Colonel F. E. Fremantle, M.P. Sir Thomas Oliver read a paper on Dusty Occupations and their Effect on the Lungs. Coal-dust, he said, did no harm; it was the stony, gritty particles that damaged the lung, intensified if bronchial catarrh or tubercle should supervene. Arsenic miners at Schneeberg in Saxony had lately begun to suffer from cancer of the lung (arsenic miners in Cornwall do not), ascribed by Ludwig to radium emanations associated with their dusty operations. Alderman Halsted (Dursley) hoped people would not mind paying a little extra for their coal in order to increase the precautions against dust in mines. Sir Thomas Oliver, in replying, mentioned that the dustiest operation he knew was making millstones in France; the men became very thirsty, drank freely, and at 40 were old men.

Mr. Sydney Tatchell, F.R.I.B.A., read a paper on Hygiene and Industry, stressing the importance of attention to the conditions of offices and to the protection of clerks, and telling how he had remodelled a City office, particularly by removing partitions and throwing large rooms open. Councillor Julyan (Poole) said sanitary authorities should take the lead in giving their clerks good working conditions. The difficulty is clerks are not protected by the Factory Acts. Dr. C. S. Thomson (M.O.H., Deptford) said he had been asked to lecture on health at Deptford, which he agreed to do if not less than 500 came to hear, and on these terms he had given several lectures. Dr. W. J. Howarth (M.O.H., City of London) said London offices were extending into basements, very dark and airless, forbidden as dwellings. He thought the present maximum height might be reckoned to the cornice, and the storeys in the roof counted extra. One difficulty was that the people in the dark offices did not themselves complain. Dr. J. J. Buchan (M.O.H., Bradford) said education in hygiene for youths was the proper way of advance. Health visitors told him that domestic servants made the best mothers. It was clear that the others must be trained. Mr. Alexander Johnston, J.P. (North British Rubber Company), read a valuable paper on Industrial Welfare, showing how welfare work had become an integral part of management. It increased output, and produced friendliness and esprit de corps. Works councils helped to prevent accidents, and by mutual understanding led to better training.

On Tuesday evening, in the Synod Hall, Sir W. Leslie Mackenzie (Scottish Board of Health) gave a lecture on the *Problem of Psycho-physical Fitness*, which, as Sir George Newman, who presided, said, was, in other words, how to raise a fit imperial race. When, asked Sir Leslie Mackenzie, was a man fit? Fitness is a pure abstraction, but in the war a direct answer had to be given when it was found that of nine men three were fit for any work, two were on a definitely infirm plane, three could do very little, and one was a chronic invalid. We could increase the number of the fit by staying the progress of disease. Tubercle was decreasing, typhoid had been nearly banished. Rheumatism still took a great toll, for nearly one-sixth of industrial debility was due to rheumatic diseases. We should concentrate on prenatal work, infant welfare, and the health of the school child. We might, if we chose, in a generation get rid of diphtheria and scarlet fever. No one need take small-pox unless he wished. So much for physical fitness. Great

advances in psychology had been recently made, and we could work better to secure mental fitness. Besides insanity we had to guard against the obsessions, unreasoning fears, bad tempers. Insanity was itself a disorder of conduct. The child lived in a world of its own, and it was the duty of the teacher to see that it learned without a jolt to adjust itself to life with others. These shocks caused mental conflict. The feeble-minded must be segregated. Mental and physical health were parts of the same problem, the man who neglected either would fail in both. In seconding a vote of thanks to the lecturer, Dr. C. J. Fernandes (Bombay) expressed surprise that England, which had taught India to escape small-pox by vaccination, seemed itself to have lost faith in the specific. Dr. Andrew Balfour moved a vote of thanks to Sir George Newman, who remarked on the benefit of the Congress in bringing together on the same plane the *servant*, the *medical officer of health*, and his masters, the members of sanitary authorities.

WEDNESDAY, JULY 22ND.

The *Section of Personal and Domestic Hygiene* was addressed by the Marchioness of Aberdeen and Temair, (the President), who said the great difficulty they still had to face was the apathy of those whom they hoped to benefit. Certainly they were dulled by the dreadful housing conditions against which many mothers were striving heroically. The Royal Sanitary Institute was doing splendid work by increasing popular knowledge. She had had experience of the interest evoked in Ireland by travelling health exhibitions with good demonstrators. Such exhibitions proved a profitable investment for local authorities which wanted support from their constituencies. In practice it was best to start with an attack on tuberculosis, and later to show the benefits of child welfare and the values of foods. She cited the example of the junior Red Cross societies, centred in Paris, which induced children to learn health as a game, thereby *speeding* up the parents. She had even heard of children in Dublin eager to be the first treated by the dentist. Such was the change wrought. The Playground Association of America for old and young was doing great work. A street with little traffic was *closed* in the evening, a paid organiser set the children playing. After a few nights the parents began to join in. They got the whole community together to tell stories, to perform plays in the children's summer and winter *holidays*. This was occurring in 680 cities of the United States, with less crime and less juvenile delinquency as the result.

Dr. Joan Rose (Edinburgh) read a paper on rickets, which elicited *from* the members a hope that proprietary starchy foods might be forbidden by law, and an intention to combat rickets by better feeding of the expectant mother.

Dr. R. A. Lyster (M.O.H., Hants), in his presidential address to the *Medical Officers of Health*, emphasised the difficulties of dealing with mental defectives, particularly if they married, and said that sterilisation had been recommended by a committee in New Zealand. The greatest hindrance to preventive medicine to-day was the inadequate instruction of young doctors in public health. A course of State medicine was needed which would harmonise the views of the profession with the *needs* of those who would be working under the National Health Insurance Act. Dr. A. K. Chalmers (M.O.H., *Glasgow*) said that the tenement system of housing on many floors was characteristic of Scotland, the cottage *system of* England. But each was now developing along the lines of the other, England building blocks of flats, Scotland providing four cottages in one block, giving each house a separate entrance. *They* could not dissociate the higher incidence of *infectious* and respiratory disease in Scotland over that *of* Wales and England from its system of housing in tenements.

In speaking to a crowded meeting of the *Representatives of Sanitary Authorities* in the City Chambers, the Lord Provost in the chair, Lieut.-Colonel F. E. Fremantle, M.P., claimed that the Government had been systematically working out a great scheme of health administration. But there was much overlapping in the departments of Government; recruiting, pensions, housing concerned various departments, and each had to decide its own policy. There should be a unified health service under the Prime Minister, like the Committee of National Defence, advisory, not executive. He proposed, and the meeting unanimously passed, a resolution pressing the Government to set up the promised Committee of Civil Research, with special emphasis on its health activities, to be applied by the various departments of Government.

Councillor W. B. Smith (Glasgow) told of the plant set up in Glasgow for providing smokeless fuel which would, he hoped, prove a commercial success, and might in addition solve the smoke problem.

In the evening the Lord Provost, magistrates, and council held a reception in the fine rooms of the College of Art, the guests being entertained with well-sung Scottish and other songs and the music of the "pipes."

THURSDAY, JULY 23RD.

At the Conference of *Port Sanitary Authorities*, Councillor W. J. Harvey, chairman of the Edinburgh Public Health Committee, the President, said that the work of these authorities was so good that attention was rarely directed to it. But it was very important as being the "coastguard of health," and that in its inspection of food from abroad it should exclude all tuberculous meat. The conditions of sailors in ships with 120 cubic feet *as the statutory* minimum were intolerable. Dr. R. M. Picken (M.O.H., Cardiff) presented *a paper on destroying* vermin on vessels. Sulphur dioxide can kill both rats and fleas. Hydrocyanic acid is quicker and, as it kills the flea on the rat's body, is useful for identification. The general *opinion of speakers seemed* to be that hydrocyanic acid, though effective, was dangerous, while sulphur (1½ lb. for every 1000 cubic feet in well-sealed ships) if properly used was as effective. Dr. W. M. Willoughby (M.O.H., Port of London) contributed *a most* interesting *paper* on the suggestions of one *James* Angier, *arraigned* as a quack, to get rid of plague in London in 1665 by the burning of sulphur. Dr. Mitsuzo Tsurumi, of Japan, read papers on Pneumonic Plague, which had again arisen among the tarbagans. Fleet Surgeon W. E. Home submitted a standard death-rate for merchant seamen, and, seconded by Alderman F. Askew (chairman, Hull and Goole Port Sanitary Committee), moved *a resolution asking* the Council again to represent to the Government that better statistics were needed of the deaths of merchant seamen, who should be brought, for purposes of health considerations, under the care of the Ministry of Health.

The *Popular Lecture* was given by Dr. C. Porter (M.O.H., Marylebone), born and brought up in Edinburgh, who declared that higher developments of health in the future were to be attained by the constant interest of the citizen in his own health, which he will keep up by occasional visits to a doctor for investigation.

FRIDAY, JULY 24TH.

At the *Closing Meeting* it was stated that the attendance had been 1640, a record number. There were 875 delegates sent by 500 authorities.

The *Official Dinner* was held on Friday evening in the North British Station Hotel, the Chairman of the Council, Sir Henry Tanner, being in the chair. Prof. Bostock Hill, proposing the Lord Provost, *magistrates*, and Council of the City, the most beautiful in the world, spoke of the success of the Exhibition which had been particularly noticeable for its demonstration of women's work in hygiene and of the Scottish apprentices in plumbing. The Lord Provost, Sir W. L. Sleigh, *thanked* the Congress for the encourage-

In answer to a question similar to that put to previous witnesses as to the case for differentiating between the eye and other organs as regards persons entitled to render remedial treatment, the witnesses quoted Mr. Bishop Harman in support of the view that the eye is the only organ of the body where by direct observation its internal condition can be fully examined.

> (Q. 17723.) As opticians we claim to be physicists, and to supply a proper physical appliance for the correction of a physical error. In our studies we aim, in addition to that, not at a knowledge of pathology at all . . . but a very high knowledge of anatomy and physiology, so extensive that we can immediately detect any departure from normal appearance or function and immediately refer any clients so affected to the trained pathologist. . . They also said that the law, as interpreted by the Lord Chief Justice in the case of Markham *v.* Thomas, imposed upon the optician the onus of detecting pathological conditions. Ever since the decision in that particular case the optician has been very anxious indeed, in his own interests, to make sure that he had the skill and ability to detect those conditions.

ROYAL SANITARY INSTITUTE:

CONGRESS AT EDINBURGH.

JULY 20TH–25TH.

THE Congress began on July 20th with a luncheon in the Students' Union, where Mr. Ewan F. Macpherson (Scottish Board of Health) remarked on the advances in hygiene which marked the progress of the Institute. The formal opening took place in the M'Ewan Hall, the chair being at first occupied by the Marquess of Aberdeen and Temair (a Vice-President of the Institute), who read a letter from the Duke of York regretting his absence. He then introduced the President of the Congress, Sir John Gilmour (Secretary for Scotland), who recounted how many-sided were the health problems of the Government and how well they had been met. He observed that Scotland was particularly easy to manage hygienically as she had always plenty of good water near her great aggregations of population; on the other hand, it was difficult to bring nurses in touch with all patients in the scattered isles. In each of its populous centres there was a university from which knowledge of hygiene was easily spread. Prof. Lorrain Smith was much struck with the personal care people were getting from health officials; the profession was coming again into personal touch with the community on the protective side too, where they seemed for a time to have lost that touch. Alderman W. Phene Neal (London City Corporation) hoped the Congress would be specially successful, as an encouragement to London, where next year's congress was to be held. Resolutions at conferences did do good. He had voted many times asking for municipal slaughter-houses, and now the last private slaughter-houses were to be closed in London. He wondered if people in general realised that 16 per cent. only of our meat was home-grown, only 14 per cent. in London, where only one loaf in ten was of English wheat.

TUESDAY, JULY 21ST.

The *Section of Sanitary Science* was opened by Sir George Newman, the President, whose speech was reported in our last issue. The other papers were on immunity and infectious disease, and great interest was taken in the Edinburgh attack on diphtheria by the Schick test and toxin-antitoxin injection, voluntary as far as the parents were concerned, but few objected; 16 cases of diphtheria had since occurred in children, shown to be positive, but not protected. Immunisation is giving very satisfactory results.

In the *Section of Industrial Hygiene* Captain W. E. Elliot, M.P. (Under-Secretary of Health for Scotland), who presided, said the capital of a nation was mainly in the bones, muscles, and grey matter of its citizens. Without health no other wealth has value. But if the power of man, as in machines, increases without improvement of his grey matter he will perish like the huge but small-brained diplodocus and its congeners. There was great loss of work by sickness; men lost more than women from diseases of the eye and apoplexy, women more than men from diseases of veins and anæmia. Regular repetitive work is monotonous—may not the present passion for betting be the outcome of monotony? When he noted the great advances in health made in recent years, the work of physicians, he was proud that he too had been a physician. He then had to leave, when his place was taken by Lieut.-Colonel F. E. Fremantle, M.P. Sir Thomas Oliver read a paper on Dusty Occupations and their Effect on the Lungs. Coal-dust, he said, did no harm; it was the stony, gritty particles that damaged the lung, intensified if bronchial catarrh or tubercle should supervene. Arsenic miners at Schneeberg in Saxony had lately begun to suffer from cancer of the lung (arsenic miners in Cornwall do not). ascribed by Ludwig to radium emanations associated with their dusty operations. Alderman Halsted (Dursley) hoped people would not mind paying a little extra for their coal in order to increase the precautions against dust in mines. Sir Thomas Oliver, in replying, mentioned that the dustiest operation he knew was making millstones in France; the men became very thirsty, drank freely, and at 40 were old men.

Mr. Sydney Tatchell, F.R.I.B.A., read a paper on Hygiene and Industry, stressing the importance of attention to the conditions of offices and to the protection of clerks, and telling how he had remodelled a City office, particularly by removing partitions and throwing large rooms open. Councillor Julyan (Poole) said sanitary authorities should take the lead in giving their clerks good working conditions. The difficulty is clerks are not protected by the Factory Acts. Dr. C. S. Thomson (M.O.H., Deptford) said he had been asked to lecture on health at Deptford, which he agreed to do if not less than 500 came to hear, and on these terms he had given several lectures. Dr. W. J. Howarth (M.O.H., City of London) said London offices were extending into basements, very dark and airless, forbidden as dwellings. He thought the present maximum height might be reckoned to the cornice. and the storeys in the roof counted extra. One difficulty was that the people in the dark offices did not themselves complain. Dr. J. J. Buchan (M.O.H., Bradford) said education in hygiene for youths was the proper way of advance. Health visitors told him that domestic servants made the best mothers. It was clear that the others must be trained. Mr. Alexander Johnston, J.P. (North British Rubber Company), read a valuable paper on Industrial Welfare, showing how welfare work had become an integral part of management. It increased output, and produced friendliness and esprit de corps. Works councils helped to prevent accidents, and by mutual understanding led to better training.

On Tuesday evening, in the Synod Hall, Sir W. Leslie Mackenzie (Scottish Board of Health) gave a lecture on the *Problem of Psycho-physical Fitness*, which, as Sir George Newman, who presided, said, was, in other words, how to raise a fit imperial race. When, asked Sir Leslie Mackenzie, was a man fit? Fitness is a pure abstraction, but in the war a direct answer had to be given when it was found that of nine men three were fit for any work, two were on a definitely infirm plane, three could do very little, and one was a chronic invalid. We could increase the number of the fit by staying the progress of disease. Tubercle was decreasing, typhoid had been nearly banished. Rheumatism still took a great toll, for nearly one-sixth of industrial debility was due to rheumatic diseases. We should concentrate on prenatal work, infant welfare, and the health of the school child. We might, if we chose, in a generation get rid of diphtheria and scarlet fever. No one need take small-pox unless he wished. So much for physical fitness. Great

advances in psychology had been recently made, and we could work better to secure mental fitness. Besides insanity we had to guard against the obsessions, unreasoning fears, bad tempers. Insanity was itself a disorder of conduct. The child lived in a world of its own, and it was the duty of the teacher to see that it learned without a jolt to adjust itself to life with others. These shocks caused mental conflict. The feeble-minded must be segregated. Mental and physical health were parts of the same problem, the man who neglected either would fall in both. In seconding a vote of thanks to the lecturer, Dr. C. J. Fernandes (Bombay) expressed surprise that England, which had taught India to escape small-pox by vaccination, seemed itself to have lost faith in the specific. Dr. Andrew Balfour moved a vote of thanks to Sir George Newman, who remarked on the benefit of the Congress in bringing together on the same plane the servant, the medical officer of health, and his masters, the members of sanitary authorities.

WEDNESDAY, JULY 22ND.

The *Section of Personal and Domestic Hygiene* was addressed by the Marchioness of Aberdeen and Temair, (the President), who said the great difficulty they still had to face was the apathy of those whom they hoped to benefit. Certainly they were dulled by the dreadful housing conditions against which many mothers were striving heroically. The Royal Sanitary Institute was doing splendid work by increasing popular knowledge. She had had experience of the interest evoked in Ireland by travelling health exhibitions with good demonstrators. Such exhibitions proved a profitable investment for local authorities which wanted support from their constituencies. In practice it was best to start with an attack on tuberculosis, and later to show the benefits of child welfare and the values of foods. She cited the example of the junior Red Cross societies, centred in Paris, which induced children to learn health as a game, thereby speeding up the parents. She had even heard of children in Dublin eager to be the first treated by the dentist. Such was the change wrought. The Playground Association of America for old and young was doing great work. A street with little traffic was closed in the evening, a paid organiser set the children playing. After a few nights the parents began to join in. They got the whole community together to tell stories, to perform plays in the children's summer and winter holidays. This was occurring in 680 cities of the United States, with less crime and less juvenile delinquency as the result.

Dr. Joan Rose (Edinburgh) read a paper on rickets, which elicited from the members a hope that proprietary starchy foods might be forbidden by law, and an intention to combat rickets by better feeding of the expectant mother.

Dr. R. A. Lyster (M.O.H., Hants), in his presidential address to the *Medical Officers of Health*, emphasised the difficulties of dealing with mental defectives, particularly if they married, and said that sterilisation had been recommended by a committee in New Zealand. The greatest hindrance to preventive medicine to-day was the inadequate instruction of young doctors in public health. A course of State medicine was needed which would harmonise the views of the profession with the needs of those who would be working under the National Health Insurance Act. Dr. A. K. Chalmers (M.O.H., Glasgow) said that the tenement system of housing on many floors was characteristic of Scotland, the cottage system of England. But each was now developing along the lines of the other, England building blocks of flats, Scotland providing four cottages in one block, giving each house a separate entrance. They could not dissociate the higher incidence of infectious and respiratory disease in Scotland over that of Wales and England from its system of housing in tenements.

In speaking to a crowded meeting of the *Representatives of Sanitary Authorities* in the City Chambers, the Lord Provost in the chair, Lieut.-Colonel F. E. Fremantle, M.P., claimed that the Government had been systematically working out a great scheme of health administration. But there was much overlapping in the departments of Government; recruiting, pensions, housing concerned various departments, and each had to decide its own policy. There should be a unified health service under the Prime Minister, like the Committee of National Defence, advisory, not executive. He proposed, and the meeting unanimously passed, a resolution pressing the Government to set up the promised Committee of Civil Research, with special emphasis on its health activities, to be applied by the various departments of Government.

Councillor W. B. Smith (Glasgow) told of the plant set up in Glasgow for providing smokeless fuel which would, he hoped, prove a commercial success, and might in addition solve the smoke problem.

In the evening the Lord Provost, magistrates, and council held a reception in the fine rooms of the College of Art, the guests being entertained with well-sung Scottish and other songs and the music of the "pipes."

THURSDAY, JULY 23RD.

At the *Conference of Port Sanitary Authorities*, Councillor W. J. Harvey, chairman of the Edinburgh Public Health Committee, the President, said that the work of these authorities was so good that attention was rarely directed to it. But it was very important as being the "coastguard of health," and that in its inspection of food from abroad it should exclude all tuberculous meat. The conditions of sailors in ships with 120 cubic feet as the statutory minimum were intolerable. Dr. R. M. Picken (M.O.H., Cardiff) presented a paper on destroying vermin on vessels. Sulphur dioxide can kill both rats and fleas. Hydrocyanic acid is quicker and, as it kills the flea on the rat's body, is useful for identification. The general opinion of speakers seemed to be that hydrocyanic acid, though effective, was dangerous, while sulphur (1¼ lb. for every 1000 cubic feet in well-sealed ships) if properly used was as effective. Dr. W. M. Willoughby (M.O.H., Port of London) contributed a most interesting paper on the suggestions of one James Augier, arraigned as a quack, to get rid of plague in London in 1665 by the burning of sulphur. Dr. Mitsuzo Tsurumi, of Japan, read papers on Pneumonic Plague, which had again arisen among the tarbagans. Fleet Surgeon W. E. Home submitted a standard death-rate for merchant seamen, and, seconded by Alderman F. Askew (chairman, Hull and Goole Port Sanitary Committee), moved a resolution asking the Council again to represent to the Government that better statistics were needed of the deaths of merchant seamen, who should be brought, for purposes of health considerations, under the care of the Ministry of Health.

The *Popular Lecture* was given by Dr. C. Porter (M.O.H., Marylebone), born and brought up in Edinburgh, who declared that higher developments of health in the future were to be attained by the constant interest of the citizen in his own health, which he will keep up by occasional visits to a doctor for investigation.

FRIDAY, JULY 24TH.

At the *Closing Meeting* it was stated that the attendance had been 1640, a record number. There were 875 delegates sent by 500 authorities.

The *Official Dinner* was held on Friday evening in the North British Station Hotel, the Chairman of the Council, Sir Henry Tanner, being in the chair. Prof. Bostock Hill, proposing the Lord Provost, magistrates, and Council of the City, the most beautiful in the world, spoke of the success of the Exhibition which had been particularly noticeable for its demonstration of women's work in hygiene and of the Scottish apprentices in plumbing. The Lord Provost, Sir W. L. Sleigh, thanked the Congress for the encourage-

ment its meeting in Edinburgh had given to preventive medicine in that city. Lord Alness, Lord Justice Clerk, proposed the delegates, and Dr. A. A. Helmi (Cairo) and Dr. J. L. Oluwole (Lagos) replied. Dr. W. J. Howarth proposed the Local Committee and thanked them for their generous and spontaneous welcome. Edinburgh was full of local patriotism and he hoped there might be as much in London next year. Councillor Harvey and Mr. Alan W. Ritchie, chief sanitary inspector, replied.

THE HEALTH EXHIBITION.

The exhibition, well displayed in the Waverley Market, was opened on Monday afternoon by the Lord Provost in the presence of 700 people. Prof. Bostock Hill, who announced the judges' awards, drew attention to the change in health exhibitions. Traps and drains were now taken for granted, and modern hygiene dealt with the individual, the school-child, and the infant. Among the exhibits were many of great value.

Queen Victoria's Jubilee Institute for Nurses showed a bed with a sick patient illustrating model nursing appliances and their substitutes as improvised for poorer homes; also the kitchen of a tenement house prepared for an emergency operation. The stall equipped by the Town Planning Committee of the Edinburgh Corporation showed a map of Edinburgh in the twelfth century; houses in a single row on each side of the High-street and Canongate, each with its garden or close stretching away behind it. The crowded closes of recent days were shown in later maps as the gardens got covered with houses and the growing city became congested within its walls. Messrs. Morrison and Son showed a most interesting enamelled iron bath and basin combined whereby the cost of plumbing was halved. It had been designed for a housing scheme and cost just below £11. There was no "overflow," the plugs of bath and basin being on a short chain, so that they could not both be closed at the same time. Messrs. W. E. Farrar (Birmingham) showed glass coverings of taps, metal concealed, and the taps of various colours to suit the bedrooms in which they might be installed. Also shown was a double trough lavatory for a factory with roses all along for hand-washing, each opened by a foot-tap. Messrs. Chance Brothers and Co. (Birmingham) showed their Calorex glass which very effectively saved the face from the scorching of a large electric light though the light came through; also Vitaglass, which lets electric light through without cutting off the ultra-violet rays. Messrs. Davidson, of Belfast, showed the Sirocco fan, which has done so much for ship, colliery, and other ventilation, and tea-drying, and was here shown removing dust from flues. Mr. James D. Bennett showed his unbreakable school desk made of iron tube, all but the bookboard and seat, in its outline, recalling a bentwood chair (bronze medal). Messrs. Fairbank Kirby (Grimsby) (they also got a bronze medal) showed their cold-drawn cod-liver oil, prepared by the method of Dr. Mellanby. Activated Sludge, Ltd., had working models showing the forcing of air into the sludge, &c., to which the Institute had awarded a silver medal. Edinburgh Corporation Gas Department showed a new gas-oven which, being set at the mark determined as suitable for the cooking in progress, prevented, by a thermostat, the temperature in the oven from rising too high. The British Women's Temperance Association and the British Social Hygiene Council showed excellent literature and diagrams for advancing their propaganda. Messrs. G. W. Harrison and Co. showed their Silent Harriap flushing cistern. A solid piston by its upward movement lifts enough water to set the syphon action going, and when it is released a copper shutter on the piston opens and allows the rest of the water to complete the flush. As the shutter and its bearings are of copper and are fixed in the piston when it is cast, it is held that the system will never be eaten away by chemical action nor require repair (silver medal). The Lacre Motor Car Co. (King's Cross, London) showed a street-sweeping brush mounted in a motor body with only a single wheel behind to facilitate sweeping out corners (silver medal). Edinburgh Corporation Electricity Department showed the baking of bread in an electric-heated oven. A remark to the manager of the stall suggesting that electricity was too expensive for cooking and other household heating, led him to say that of course it depended on the price of current, but that a county asylum had had an interesting experience. It made its own electricity originally for lighting with carbon filament lamps, but as these were replaced by metal filament, and these by gas-filled lamps, there was so much electricity to spare that the kitchen, cooking for 1000 persons, patients and staff, was outfitted with complete equipment, ovens for bread baking, fish fryers, vegetable steamers, roasting ovens, &c., that this was found to be practicable with only its existing generating plant, and the change to electricity has ever since given complete satisfaction. At stall No. 54, North British Rubber Co., Ltd. (Edinburgh and London), was seen a novel and easily cleaned teat for feeding-bottles. There is no teat; that is replaced by a grooved strip of rubber which, doubled, passes through a slot in the dome of the cap; the child has the loop in his mouth and sucks the milk easily through the channel formed by the grooves. Once the knack of adjustment has been learned there is no difficulty in cleaning the teat and putting it again in use. Silver medals were awarded to Messrs. Southall, and to Hoover, Ltd., for their suction sweeper. Messrs. Parsons, of 315, Oxford-street, London, showed panels of their enamels of wonderful brilliance which won a bronze medal.

(*To be continued.*)

Reviews and Notices of Books.

SURGICAL TREATMENT OF PULMONARY AND PLEURAL TUBERCULOSIS.

By J. GRAVESEN, M.D., Medical Superintendent, Vejlefjord Sanatorium, Denmark. With a Foreword by Dr. S. VERE PEARSON. London: John Bale, Sons and Danielsson, Ltd. 1925. Pp. 155. 10*s.* 6*d.*

THERE are several books and countless papers on the surgical treatment of pulmonary and pleural tuberculosis, but most of them are out of date, so rapid has been the advance in our knowledge of this subject. Dr. Gravesen's book accordingly fills a gap.

It is proper and fitting that this book should have come from Vejlefjord Sanatorium, for it has probably done more than any other institution in the world to promote the collapse treatment of pulmonary tuberculosis, and its first chief, Prof. Saugman, Dr. Gravesen's predecessor, was a conservative revolutionary, who converted the Dettweiler conception of masterly inactivity in the sanatorium into an elaborate system embracing surgery as well as medicine. During the last 20 years of his life Saugman was untiring in his efforts to bring to perfection artificial pneumothorax and, later, the operation of extra-pleural thoracoplasty, thoracoscopy with cauterisation of pleural adhesions, apicolysis, and many other daring incursions into the surgery of the lungs. Dr. Gravesen, who served as his assistant for many years, has made good use of the ample material and experience at his disposal, summarising in orderly fashion the essentials of his subject. Only by a severe elimination of unimportant details could he have condensed his matter into 155 small pages; and to those who during the past decade have attempted to struggle with the truck-loads of literature on this subject, this achievement of condensation is most impressive. The description of the technique of the induction of a pneumothorax should be read by all who would practise this treatment, and who may be tempted to approach it with imperfect equipment. A considerable part of the book is devoted to pleurisy, and as tuberculous pleurisy with effusion is often encountered by the busy practitioner, he would do well to learn the most modern methods of treating this condition, improper treatment of which may seal the patient's fate many years later. The procedure which the author recommends in such cases is gas replacement which allows of evacuation of the peccant fluid and yet maintains that compression of the lung which is most desirable at this stage. It would be interesting to learn in what proportion of cases of tuberculous pleurisy with effusion in Great Britain this simple operation of gas replacement is practised.

Dr. Gravesen duly emphasises the importance of combining sanatorium treatment with surgical activity instead of allowing the one to become a competitor of the other. To encourage an alliance instead of a competition between these forces he foresees the need for introducing hospital-like conditions into the sanatorium, the conventional traditions of which must be modified so that in the future it will provide not only fresh air and rest, but also such widely different remedies as surgery, artificial light, chemo-therapeutic drugs, and whatever else medical research may give us in the future. In connexion with the author's reference to chemotherapy, it should be noted that he has used sanocrysin since April, 1924, without having lost faith in it, and he discusses the possibilities of combining or interchanging sanocrysin and surgical treatment. Sanocrysin is, of course, still on trial, but the surgical treatment of pulmonary and pleural tuberculosis has passed the experimental stage, and Dr. Gravesen's book will remain a standard work on this subject for years to come.

TETANY.

La Tétanie Infantile. By R. A. TURPIN. Paris: Masson et Cie. 1925. Pp. 224. Fr.16.

THIS is a work of considerable importance and interest, not all of which is indicated by the title. The scope of the book is by no means limited to carpopedal spasm, but extends to most of the symptoms commonly described as spasmophilic (*tétanie latente*), and the author's observations have important bearings on the whole question of the nature of rickets. The first part of the book consists of a summary of the numerous researches which have been carried out in recent years on metabolism in tetany, following parathyroidectomy and arising from other causes. The question of calcium metabolism naturally occupies a large part of this chapter; Dr. Turpin demonstrates the conflicting results of the experiments referred to, and asserts that tetany can no more be accounted for by a pure hypocalcæmia than by excess of guanidine in the blood.

The author's own observations are presented in the form of a comparative study of three forms of tetany: (1) arising after parathyroidectomy; (2) produced by voluntary hyperpnœa; (3) occurring in children, usually associated with rickets. The investigation was principally concerned with the alterations which take place in the electrical reactions of the affected neuromuscular units, and in the calcium metabolism. The author considers that the most characteristic feature of the electrical reactions is alteration of the chronaxie. In latent infantile tetany (spasmophilia) this takes the form of instability, usually increase. In tetany following removal of parathyroids or evoked by voluntary hyperpnœa there is a very considerable increase, which is present before the spasm develops, rises to a maximum during the attack, and diminishes as the spasm subsides. The changes which are found in the blood in tetany are described in detail, and illustrated by tables showing the hydrogen-ion concentration and calcium-ion content in a series of cases. The author's view is that the essential change which precedes the spasm in all forms of tetany is an alteration of the acid-base relation in the direction of hyperalkalinity, resulting in a fall in the ionic-calcium content of the blood, though not necessarily in the total calcium content. Treatment is to be directed to the correction of this alkalinity, and for this purpose ingestion of ammonium chloride and exposure to ultra-violet rays are the most effective measures. On the exact relation between tetany and rickets the author is somewhat reticent, though rickets appears as an almost constant feature of the cases which he describes; his work may perhaps strengthen the opinion of those who regard tetany as essentially a manifestation of rickets. A problem of equal interest is presented by the relation of neuropathic heredity in spasmophilia with the biochemical processes described in this work.

The value of the book is greatly increased by a comprehensive bibliography.

MANUAL ON MIDWIFERY.

Sixth edition. By THOMAS WATTS EDEN, M.D., F.R.C.P., F.R.C.S., Consulting Obstetric Physician to Charing Cross Hospital; and EARDLEY HOLLAND, M.D., F.R.C.P., F.R.C.S., Obstetric and Gynæcological Surgeon and Lecturer on Obstetrics and Gynæcology, the London Hospital. London: J. and A. Churchill. 1925. With plates and 303 illustrations in the text. Pp. 704. 21*s*.

THE preparation of the completely revised sixth edition of this standard text-book of midwifery has been entrusted by the author to Dr. Eardley Holland, who is responsible for the many alterations in it. Although much new matter has been added and certain parts rewritten, it has been found possible to reduce the original number of pages by 40, a relief for which the student will be grateful. The book is now divided into nine parts. Parts VII. and IX. are new. The former deals with "Diseases, Injuries, and Death of the Fœtus," asphyxia neonatorum being now included here. This is a valuable addition to the book as it represents the results of Dr. Holland's well-known investigations on this subject. He makes a strong plea to the medical profession for the adoption of the terms "live-birth" and "dead-birth" in preference to "still-birth." Pulmonary respiration and not cardiac beat is taken as the sign of the former, whereas death of the fœtus before it has breathed, even if its heart is beating at birth, is adopted as the definition of "dead-birth." In Part IX. a brief description is given of the statistics of maternal mortality, followed by an excellent account of the methods and purpose of antenatal supervision. This important section is wisely placed at the end of the book, for the student at this stage will be the better able to appreciate the great advantages of efficient antenatal care, not only to the pregnant woman, but also to the practitioner.

The management of normal pregnancy is dealt with in Part I., where new sections have been added on the functions of the placenta and on the changes in the maternal metabolism during pregnancy. Attention is here drawn to the diagnostic value of X rays, not only in the differentiation of an early pregnancy from such conditions as a vesicular mole or fibroids, but also in the determination at full term of the presentation and lie of the fœtus, particularly in hydramnios or multiple pregnancy. It is also of value in excluding premature twins or a monster in cases where a Cæsarean section is contemplated, for anencephaly is easily demonstrable, and the degree of the ossification of the bones will give some idea of the fœtal age. Three illustrative radiograms are admirably reproduced, the most interesting of which depicts the spine and leg of a fœtus at the sixteenth week. This may well be the earliest positive sign of pregnancy, but we doubt whether a negative result at this stage is of much value. The section dealing with the toxæmias of pregnancy, including eclampsia, has been largely rewritten, and Dr. Holland makes an impartial résumé of modern views. For himself he still regards routine clinical experience as a more reliable guide than biochemical investigation. Part IV. (Abnormal Labour) now includes occipito-posterior positions with extension of the head, this position being diagnosed "when the second stage of labour has lasted three hours—or less if the powers of labour have begun to fail—and there is no sign of forward rotation occurring," the position before this being dealt with in Part III. (Normal Labour). This division may perplex the tyro. A welcome description is given of Buist's pad and binder method of rotating the occiput during the last few weeks of pregnancy.

The subject of puerperal infection is dealt with in a thorough and up-to-date manner. The old division into sapræmia and septicæmia is discarded, and the infections are grouped into slight and severe, the latter with or without secondary septicæmia. "Primary septicæmia" is reserved for those fulminant cases in which the infection becomes generalised from the first. Great stress is laid on careful bacteriological examination of the uterine contents, and an excellent description is given of the technique. Dr. Holland is not convinced that auto-infection plays any part in the severer forms, but he assigns a definite place to latent gonococcal infection. The portion of the book dealing with Cæsarean section includes a short description of the two lower-segment operations which, the author claims, are especially suitable for cases in which infection has occurred or is suspected. There is less risk of adhesion, and so far no case has been reported of rupture of a scar in the lower uterine segment; whereas in a collective follow-up investigation into 1000 cases or more carried out by Dr. Holland in 1920, it was found that rupture of the scar occurred in 4 per cent. of cases after the classical operation.

This edition of the manual bids fair to maintain its position as one of the best students' text-books of obstetrics.

Medical Electricity for Nurses.

By **Harold Wigg**, Radiographer, Royal Buckinghamshire Hospital. London: The Scientific Press, Ltd. 1925. Pp. 196. 6s.

This little book has been written to assist the nurse in an electrical department to acquire a working knowledge of the uses of electricity for medical purposes. In less than 200 pages the author deals with physical principles, the sources of current electricity, the effects of electricity on the body, faradic, galvanic and sinusoidal apparatus, the methods of applying these currents, medical and surgical ionisation, muscle and nerve testing, radiant heat and light, X rays, static electricity and high-frequency, diathermy, and the electrical circuits in certain surgical instruments such as the cystoscope. An index of electrical treatment concludes the book. We fear that in attempting to convey to the average nurse an intelligible exposition of all branches of medical electricity and of the relevant parts of chemistry and physics in so small a book the author has undertaken an almost impossible task. He has written clearly, and in a manner well suited for the worker with some preliminary knowledge of science. For the nurse a more colloquial description and the frequent use of analogy would have been helpful.

Latin on the Direct Method.

By **W. H. D. Rouse**, M.A., Headmaster of the Perse School; and **R. B. Appleton**, M.A., Chief Classical Master at the Perse School. London: University of London Press, Ltd. 1925. Pp. 226. 7*s.* 6*d.*

If the teaching of languages, alive or dead, on the principles so lucidly expounded in this book were to become universal, we should hear less about time wasted on the study of the classics, and have gone far to roll away a national reproach. The results actually obtained by the direct method in the Perse school, as here exemplified, are astonishing, and the book deserves to be read by all concerned in education. It is plain that for the fortunate boys in that school the learning of Latin is not attended by terrors, but is full of lively interest.

JOURNALS.

Journal of Pathology and Bacteriology. Vol. XXVIII., No. 3. Pp. 397–539.—The Action of Sensitised Antigen in the Production of Specific and Isophile Hæmolytic Immune Body, by T. Iijima (Tokyo). There has been a good deal of difference of experience as to whether antigens saturated with specific immune body act as efficient stimulants for antibody production, whether in other words the antigen-immune-body combination will dissociate in vivo like a neutral toxin-antitoxin mixture. The author's experiments with hæmolysins show that fully saturated red corpuscles have a very small antigenic effect.—The Nature of the Acquired Resistance to Bacteriophage Action, by F. M. Burnet (Melbourne). If a large bacterial population is acted on by a bacteriophage a small number of individuals escape the lytic action and give rise to similarly resistant descendants. d'Hérelle interpreted this as an acquisition of immunity to a parasite. The author shows that this is unlikely and explains the phenomenon in terms of the bacteriophage being a catalyst for the normal autolytic ferments which are concerned in fission, showing that the acquisition of resistance is accompanied by the production of long undivided bacillary forms. In a second paper the idea is developed that the differences between different bacteriophages are due to the readiness with which they are adsorbed on to the bacillary enzymes.—Experimental Pneumococcal Infections of the Lung, by J. F. Gaskell (Cambridge).—The Thyroid in Experimental Tuberculosis, by S. R. Gloyne (London). The thyroid in man is surprisingly immune to tuberculosis; the same is true of the guinea-pig, less so in the rabbit. Thyroid preparations have no ill-effect on tubercle bacilli in vitro nor any curative action on infected animals, nor is the natural resistance of the white rat influenced by thyroid medication. The immunity of the gland is possibly due to some anatomical cause.—Attempts to Transmit Epidemic Encephalitis to Rabbits, by J. H. Dible (Manchester). Failed in ten cases. A fresh pitfall of abnormal appearances in the brains of normal animals is described.—Immunological Notes, by A. T. Glenny, O. G. Pope, H. Waddington, and U. Wallace (Beckenham). The ratio between the in vivo and the in vitro antitoxin values is not constant as Ramon claims. In making Ramon tests care must be taken not to be misled by a non-specific flocculation which may occur at a point in the titrations far removed from the true value. The relative strength of two batches of antitoxin may vary according to the toxin used for titration. Many diphtheria toxin-antitoxin mixtures can be greatly diluted without much loss of antigenic efficiency; beyond a certain point there is no advantage in increasing the dose. Strong diphtheria toxin cannot always be relied upon to keep; dilutions made up ready for the Schick test are very easily destroyed by shaking with air; half-full bottles cannot be transported safely even a short distance. Phenol of about 5 per cent. strength destroys relatively more antitoxin than toxin in a mixture which may be thus converted from a neutral to a toxic preparation; apart from this toxin-antitoxin mixtures are stable enough. High-grade tetanus antitoxin is best produced by giving horses a few preliminary doses of toxin and then resting them for at least a month, after which they rapidly respond to further doses.—The Excretion of Water Urea and Chlorides in Experimental Oxalate Nephritis, by J. S. Dunn and N. A. Jones (Manchester). In the tubular nephrosis produced in rabbits by oxalate poisoning urea retention may be relieved by the copious administration of water and the kidney has no difficulty in excreting extra salt at the same time. It is suggested that the urea retention is due to the damaged tubules being unable to prevent the indiscriminate reabsorption of the glomerular filtrate and all its constituents.—The Relief of Experimental Arterial Anoxæmia by Compressed Air, by C. F. Nelson and P. Woodard. Anoxæmia produced by unilateral pneumothorax or the intratracheal injection of gum solution can be largely removed by compressed air at about 21 lb. pressure.—The Preparation of Certain Substituted Ureas and their Use in the Treatment of Trypanosomiasis, by T. H. Fairbrother, F. A. Mason, W. H. Perkin, and A. Renshaw (Manchester). A preparation made according to Fourneau's formula for Bayer 205 had marked trypanocidal properties on *T. equiperdum* in mice.—An Improved Method of Mounting Pathological Specimens in Flat Celluloid Cases, by C. M. Acland (Cardiff).—The Temperature of White and Black and White Rats, by C. Price-Jones (London). Useful data for 200 normal animals; the range is from 97° to 103°.—Sarcoma of the Ampulla of Vater without Jaundice Leading to Acute Pancreatitis, by H. H. Moll (Leeds).

The Patient.

This simple treatment gives relief from pain in Entero-colitis

IN Entero-colitis, where there is pronounced muscular rigidity and pain, an application of Antiphlogistine applied hot and thick over the entire abdominal wall, not only relieves the pain, but proves a valuable adjuvant to internal medication.

The sustained heat of Antiphlogistine produces a depletion of the enteric and peritoneal vessels and stimulates the solar and hypogastric plexuses.

In Entero-colitis, or any affection involving deep-seated structures, the *genuine* Antiphlogistine, by its peculiar property of maintaining a uniform degree of heat upwards to 24 hours, stimulates the cutaneous reflexes, causing a contraction of the deep-seated, and coincidentally, a dilation of the superficial, blood-vessels.

Over 100,000 Physicians use the *genuine* Antiphlogistine—it is the world's most extensively used ethical proprietary.

THE LANCET.

LONDON: SATURDAY, AUGUST 1, 1925.

HOSPITAL ADMINISTRATION IN ITS BROADER OUTLOOK.

IT is 50 years since the Public Health Act of 1875, the charter of English preventive medicine, was placed on the Statute Book. A long struggle had led up to its enactment and the way for its passage had been paved by the work of pioneers who were not always popular. The efforts of Lord SHAFTESBURY, the factory legislation of the forties, the writings of CHARLES KINGSLEY, under the name of Parson Lot, and the steady education of public opinion by a host of other writers and speakers culminated in a new outlook. Finally, at the end of this period the discoveries of PASTEUR and LISTER revolutionised our views on infective disease. To read through the clauses of the 1875 Act and the statutes, such as the Rivers Pollution Prevention Act, which followed immediately after, is to get a historical view of the effort which was made by the sociologists of the day to attain to a healthy standard of living. With the passing of the Public Health Act there came to an end the age-long practice of laissez faire, which held that a man might do what he liked with his own, and that his doings, even if inimical to health, were no concern of his neighbours and least of all of the State. Throughout this initial period of reform we may trace three main lines of progress: (1) the attempt to make our expanding industrial system safe and healthy for the workers; (2) the endeavour to improve the sanitation of rapidly growing townships with their tenement dwellings—the word slum is a product of this period—which the new industries were calling into existence; and (3) the task of applying the new standards of cleanliness, sterilisation, disinfection, and isolation, which the work of PASTEUR and LISTER had introduced into infective and epidemic disease. Alongside these reforms there had been slowly growing up a public conscience on the question of poverty and destitution, and it is the modern reflection of this feeling which finds expression in the Social Service Department of the hospital.

No country in the world has witnessed such efforts as are made in our islands to relieve sickness and poverty by voluntary means, but much of this effort can only be described as indiscriminate charity; and it was inevitable that there should follow in the wake of the sanitary reforms, marking the closing years of what ARNOLD TOYNBEE termed the industrial revolution, an attempt to understand and relieve the causes and results of poverty. About the time of the passing of the Public Health Act the development of the University Social Settlements under the influence of the late Canon SAMUEL BARNETT and TOYNBEE, and the foundation of charity organisation societies, began to emphasise the importance of understanding these questions. To use the words of Canon BARNETT, it was necessary that "citizens should learn to understand the lives of each other," and so, gradually, the State came to realise, through the pressure of hard facts, that the care of its less fortunate citizens could not be left to indiscriminate charity. The legislation of this century, therefore, has seen a great increase in all measures for sociological amelioration. The care of the blind, the deaf, the epileptic, the feeble-minded, and the insane was an essential first step in the work in which our example has been followed by other nations, but we have now gone much further and have recognised that the school child, the child of pre-school age, and the expectant mother must also be the concern of the State if a healthy standard of living is to be maintained. It would be difficult to assess in actual figures the value of the great voluntary hospitals of this country in this movement, but in medical education, in research, in the high standard of clinical practice which they have maintained, the hospitals have made no small contribution. Great as these contributions have been there remains much yet to be done. Clinical practice and surgical treatment have been raised to a high level, but there is still a vast work in front of us in correlating the sociological causes of disease. In this matter the hospitals may have been slow to act, but their hands have always been over-full. It may perhaps be considered that this particular phase of a vast set of problems lies outside the scope of the hospitals' work, but at every stage in the progress of medical research, especially in clinical research, it becomes clear that the patient's habits and manner of life, his environment, his work, and his opportunities for a healthy life are intimately relevant to his treatment.

A reference to the reports of hospital almoners—those most important officers of the Social Service Department of the institution—makes this clear, especially in special departments where a preliminary sorting of cases has already taken place. The more carefully cases are followed up by home visitation and inquiry, the more it is realised that the financial side of the work forms only a small part of the Social Service Department of a hospital. It is true that the prevention of abuse soon became one of the essential needs and cardinal rules of the early days of hospital administration, but a great deal has happened during the last quarter of a century, especially as a result of the war, to alter the point of view of financial inquiry. Indeed, to a certain extent, it can be said inquiry into hospital abuse may obscure real sociological issues. The work of the Social Service Department, if it is to be interpreted rightly, is an essential part of clinical research, and from the point of view of medical education the sociological background must have a bearing on all teaching, whether clinical or preventive. General practice to-day is becoming more and more preventive and educational in its outlook, and the youngest student sees the narrow limits of the palliative measures with which a past generation had to be content. Thus the outlook is steadily changing. In the past too much stress has been laid on rules and regulations, especially negatives—the things which patients must not do. Nowadays, stress is being more and more laid on the positive educational side of hygiene. The modern patient has had an opportunity of acquiring a knowledge of elementary hygiene and physiology in school and in the popular science press, and he is keen to know the reasons for things and able to appreciate their importance and significance. The period under review has seen the introduction of many new words in sociological literature; preventive medicine is by no means the happiest of these. We need a term which is wide in its embrace of all the problems and is educational and constructive in its outlook.

CHOLECYSTOGRAPHY.

THE application of X rays to the problems of diagnosis finds ever new fields of usefulness. One of the latest is the mapping out of the gall-bladder or cholecystography. The investigation of hepatic function by means of dyes is not itself a new method, for it was introduced 12 years ago by ROWNTREE, HURVITZ, and BLOOMFIELD,[1] who administered phenoltetrachlorphthalein intravenously and noted the rate of its appearance in the fæces. The substance is removed from the circulation by the liver and excreted in the bile with the result that, in conditions where the excretory function of the liver is impaired, the appearance of the dye in the bowel becomes delayed. On account of the variable rate of action of the intestines in different individuals the test as devised by ROWNTREE was found unsatisfactory, but McNEIL,[2] AARON, BECK, and SCHNEIDER,[3] FRIEDENWALD and GANTT,[4] and other observers made use of the duodenal tube to recover the dye, and were able to establish the method as a useful one. In normal persons the dye, given intravenously, appears in the duodenum in about 13 minutes. More recently, FIESSINGER and LONGCHAMPT,[5] working in Prof. CHAUFFARD'S clinic, have further modified this test. Giving the dye intravenously, they take a sample of blood from the patient 20 minutes later and, by a colorimetric method, observe how much of it has been withdrawn from the circulation. They point out that the kidney as well as the liver serves as a path of excretion for the substance, but, as the amount lost by this route is small, the source of error is not serious. They do, however, criticise the method in that it gives information concerning one aspect only of hepatic function—namely, the excretory process. The great practical value of the method dates, however, from the discovery by GRAHAM that radiograms of the gall-bladder could be obtained by the use of this and similar substances. GRAHAM and COLE[6] showed last year that the intravenous administration of the sodium salt of tetrabromphenolphthalein or tetraiodophenolphthalein led, in the course of a few hours, to the appearance of an opacity in the gall-bladder enabling that organ to be examined radiographically.

Clinically this method of examination, here not improperly known as "Graham's test," has been exploited with good effect at the Mayo Clinic, and Dr. RUSSELL D. CARMAN communicated to the recent International Congress of Radiology a paper (which appeared in THE LANCET of July 11th) setting out the technique adopted, and giving some noteworthy figures of its employment in the diagnosis of diseases of the gall-bladder. At the Mayo Clinic this method of investigation has been employed in more than 1100 cases during the past 15 months, and in a large number of the cases the findings have been put to the test of operation. The substances used in Dr. CARMAN'S observations were sodium tetrabromphenolphthalein and sodium tetraiodophenolphthalein, given either by oral or intravenous administration, and the gall-bladder region was examined at certain times after the administration—namely, at the fifth, eighth, and twenty-fourth hour after giving the dye. The intravenous method was found to require strict preparation and diet during the period of examination. It gives rather more dense shadows than the oral method, but it not infrequently produces some local or systemic reaction, which may be severe. The oral method does not entail any special preparation or diet, and does not give any serious systemic reactions, though nausea and purgation sometimes occur. These effects are less common with the bromine salt than with the iodine. In consequence, Dr. CARMAN at present advises the oral use of the bromine salt as a routine method, but he uses the iodine combination intravenously to check the results in doubtful cases. The usual appearance in normal cases is an increase of intensity of the shadow followed by a diminution. In regard to the results obtained in diseased conditions, Dr. CARMAN finds that failure of the gall-bladder to fill with the dye sufficiently to cast a shadow is the most important abnormal indication, though persistent faintness of the shadow is almost equally suggestive of abnormality. Mottling of the shadow may be due to gall-stones; in some cases the shadow of the stones is denser, in others lighter than that of the dye; but gas in an overlying section of bowel may give an appearance of misleading similarity. As might be anticipated, the positive findings are of more value than the negative, and normal appearances with cholecystography must not be taken as excluding disease of the gall-bladder.

The Mayo Clinic results are sufficiently striking to warrant more extended trial of the method, which promises to give results of equal value to pyelography and to the method of investigation of the kidney by X rays after injection of oxygen into the peri-renal tissues. Why certain dyes should be opaque to the X rays remains obscure, but it would appear that it is the sodium and halogen elements in them that are responsible, the linkage with phenolphthalein serving to form a molecule which is excreted by the biliary tract. Further inquiry in this direction might also repay the trouble.

LABORATORY RESEARCH IN MENTAL DISEASE.

IN his presidential address to the Medico-Psychological Association of Great Britain and Ireland, which we print in abstract on another page, Sir FREDERICK MOTT enforced on medico-psychologists the duty of practising medicine in its broadest sense. Faced with an abnormal psychic state, inquiry should be made after a bodily condition which might be acting as cause or contributory factor. The annual report of the laboratory under the direction of the *Birmingham* Joint Board of Research for Mental Diseases, which has just been issued, gives a good example of such inquiry. The work of the laboratory during the year ending March, 1925, has been to develop lines of research upon the basis of endocrine functions; special attention has so far been directed to the thyroid gland, and details are given of the basal metabolism determinations and the analyses of thyroid gland for iodine content. There has been an inquiry into the action of certain hypnotic drugs upon animals with respect to the physiological action and the effect upon the general health and well-being of the animals. Routine serological, bacteriological, and chemical work has been done for the clinical staff of the Rubery and Hollymoor Hospitals; chiefly from the gynæcological, ear, nose and throat, and dental departments, and also for the purpose of investigating the occurrence of a few cases of typhoid in each institution; this latter work is still in progress. One hundred and thirty-four specimens from the Monyhull Colony have also been examined, especially in relation to the recent dysentery outbreak. Other work includes post-mortem examinations, the collection of material for histological and chemical examination, and of specimens likely to be of interest for future study. In view of the probable association between chronic sepsis and disturbed endocrine function the bacteriological work has become part of the research and has largely occupied the resources of the laboratory. The determination of the basal metabolism in the special respiration chamber has been improved upon both in procedure and in refinements of the apparatus, which has been perfected in the laboratory. There have been 90 determinations made of 22 patients and 11 nurses; and of these 4 patients and 1 nurse showed metabolism exceeding 110 per cent. of the standard, the highest being 125 per cent., and 8 patients and 4 nurses showed metabolism below 90 per cent. of the standard—the lowest, a patient, being just under 50 per cent. of the standard; the remainder are within 90–110 per cent. of the figures given in the Harris and Benedict tables for standard metabolism. One patient with defective metabolism was examined on ten occasions when only slight variations were found between 60 and 70 per cent. of the standard. The work will be made the subject of a paper for publication.

The investigation of the iodine content of thyroid glands previously carried on at the pathological laboratory of the London County Mental Hospital at the Maudsley Hospital has been transferred to Birmingham and is still in progress. Although a number of methods for the estimation of iodine are published, none of these has proved entirely satisfactory, and an original method for the accurate quantitative estimation of the iodine has been devised. It is found that there is a great variation in the iodine content—from 1½ to 44 milligrammes per gland—which corresponds fairly well with the result previously obtained as to the extreme limits but is more accurate in respect of individual cases. The chemical results are being correlated as before with the histological investigation in each case. A large number of organisms have been isolated and classified for reference by their sugar reactions. Organisms of the typhoid-dysentery class are also tested by their agglutination reactions; a few animal inoculations have been made for diagnostic purposes. Examination of sera for typhoid agglutination is to be extended to cover all the patients in the two institutions. A large number of vaccines prepared from carefully isolated identified and purified organisms are now on trial. Three cases of puerperal sepsis have been investigated by the laboratory—one of which showed at autopsy a thrombosed inferior vena cava with a generalised infection of *B. lactis aerogenes*; another showed during life a bacteriæmia of a Gram-positive coccus. From this organism a vaccine was prepared and the patient's brother immunised in preparation for a blood transfusion; transient good results in this case followed injection of aseptic guinea-pig serum-complement in conjunction with polyvalent anti-streptococcal serum.

It is interesting to note in view of the demonstrated sepsis of the mouth and nasopharynx that 23 of 30 specimens of test-meals showed no free hydrochloric acid. Examination of the fæces has revealed many varieties of organisms. Streptococci are present in many cases, occasionally in pure culture. *B. typhosus* has been found in six cases, para B in one case, *B. aertrycke* (mutton) one case, *B. dysenteriæ* "Y" in two cases (the latter from Monyhull). A large number of organisms other than *B. coli* are often found, which do not fall into the pathogenic groups by reason of their sugar reactions. *B. friedländer* often occurs in groups of cases—*e.g.*, 9 out of 20 in one ward, and *B. cloacæ* has been found in a blood culture in one case on two successive occasions; this suggests that organisms usually considered "normal," or at least non-pathogenic, may multiply and cause disturbance in debilitated patients such as those who are commonly met with in mental hospitals. A large amount of material has been collected for histological examination, but on account of pressure of other work it has not been practicable to proceed far with this department at present. A number of blood-sugar analyses have been made of specimens taken from hospital patients in the fasting stage with a view to demonstrating cases of definite hypoglycæmia. The sugar was determined by a modification of Calvert's method. Of 78 specimens tested, 9 gave results of over 0·12 per cent. of glucose, and 29 gave results of less than 0·09 per cent., including 14 under 0·08 per cent. Other work in progress includes the quantitative estimation of the fat, lipoid, and cholesterol content of suprarenal glands obtained at autopsies and correlations with micro-chemical tests and histological structure.

The value of this steady scientific research into the physical disorders underlying mental disease is unquestioned. It is to the laboratories of mental hospitals that psychiatrists are looking for some explanation of the tangled skein they seek to unravel. At present the work is too new for far-reaching conclusions to be drawn, but before long it should be possible to correlate the findings of the various workers.

Annotations.

"Ne quid nimis."

HYGIENE IN FACTORIES.

LAST week we noted some of the more general aspects of the report of the Chief Inspector of Factories and Workshops for the year 1924. The experiment of employing women and young persons on the system of two shifts permitted by the Act of 1920 has not had a fair trial yet owing to trade depression. So far, however, as it has been adopted, difficulties of enforcement have not been experienced, some economic advantage has followed, and, in certain cases, workers have expressed a preference for this method of work. For the most part permission to work the system has been made provisional on good welfare conditions. When trade improves this interesting system will be carefully watched. The general progress in the welfare movement now fixes it as firmly established; it is spreading and broadening; dental surgeries are being started; whole time nurses are being employed; in some cases medical service is being retained; in addition to the more usual canteen and recreational activities.

Sir Thomas Legge tells of the close eye kept by his medical staff for new occupational risks as novel processes are started, and for any relaxation in efforts to prevent well-recognised industrial disease. Lead poisoning has increased, largely due to ship-breaking in which fumes from old paint arise as the plates are cut by the oxy-acetylene flame; protection here is particularly difficult. A method of detecting lead absorption by the presence of punctate basophilia, which promises to be of practical value, has been worked out by Dr. A. Sellers. The recognition of cancer among mule-spinners has led to associating the occurrence of skin epithelioma with exposure to oil in other occupations, such as machinists, engine tenters, and brick pressers. Among the spinners 20 years was the minimum exposure. There seems no reason why, now that the danger is recognised, these cases should not all be avoided. Various investigations have been made into the occurrence of dermatitis, due to dyes, alkalis, oil, sugar, nickel salts, and other things; "barley itch" among dock labourers was ascribed to *Pediculoides ventricosus*. The campaign against dust, particularly that of fine silica, is being actively pursued; a recurrence of weavers' cough, a form of aspergillosis, is reported.

The number of girls, 102,217, medically examined for certificates of fitness again exceeds that of boys, 100,334; it raises the question as to what is happening to the boys. Welcome news is given regarding the provision in all factories for first-aid, made compulsory by Section 29 of the Workmen's Compensation Act, 1923. Response to the new requirement has been astonishingly rapid and marked by goodwill and general interest; the standard of equipment is high and such ancient and dangerous remedies as carron oil are being rapidly discarded. Education in its use is still needed, as we read that of 375 septic cases investigated, 216 had not had first-aid treatment. Notwithstanding the rapid increase in the use of electricity, accidents from this cause keep surprisingly low. The remarkable fact is reported that severe accidents at very high pressures, although causing permanent injuries, may not be fatal; thus out of 37 such cases only six were fatal. A special investigation into dust arising in dealing with grain cargoes throws the blame for the acute irritation of the upper air passages, which is experienced, upon fine hair particles derived from the grain to the exclusion of contamination with dirt and debris; the application of efficient exhaust plant should prevent escape of the dust. Recommendations are made accordingly.

The report concludes with an interesting account of the Government anthrax disinfection station for wool and hair at Liverpool. Notwithstanding abnormal difficulties during the trial period, the disinfection process which depends upon formaldehyde has proved unquestionably efficient. No case of anthrax has resulted from, or been imputed to, any of the materials disinfected, even though, from 1921–24, the material amounted to 8,300,000 lb. The cost per pound in 1924 was only 1½*d.* Unfortunately the process is not being adopted in other countries. In England the industrial anthrax problem has always concerned wool; in other countries hides and skins are more to blame. Thus in the nine years 1912–20 there were 372 cases from wool, as against 156 from hides and skins, but for 1922–24 there were only 52, as against 54. Wool sorters' disease seems within sight of abolition with us.

THE PLURAL OF VIRUS.

A GREAT pathologist once said that he thought the most fruitful and inspiring moment of his undergraduate career was his first introduction to "nucleated blastema" in which he ever afterwards found comfort at moments of stress. Everyone will have their own feelings about words and phrases which make a personal appeal to their own individuality; it might be a nice point whether one would prefer to sit under the professor of "pastoral theology" or his brother of "rural economy"; no one of taste could deliberately prefer the discourses of the professor of "American history" or of "biochemistry." And just as there are words which one is glad to meet and greet with a friendly smile, so there are expressions which almost everyone dislikes as they dislike the sight of some horrid and monstrous deformity. The disposal of human defectives is a difficult and often a repugnant business. What is to be done with verbal defectives such as the plural of virus? The word is come lately into pretty common use and for the good reason that it describes as handily as any other word a group of infective agents about whose place and nature and significance there is a certain amount of doubt. And so it becomes increasingly convenient to mention them in the plural if one is to put technical terminology to its proper use as a shorthand. But who can willingly tolerate "viruses"? The Society for Pure English, of which Dr. Robert Bridges is the moving spirit, prints in a recent tract (XIX., 1925, p. 36) a note by Mr. C. T. Onions (reproduced in the issue of the *Journal of Pathology and Bacteriology*, reviewed on another page), which concludes that there is no alternative. "Neuter pelagus and virus" is a jingle of our youth which remains with us; but the attempt to use "vira" seems ultra-pedantic and, in fact, there is no evidence that this was the classical plural, since the word is recorded only in the singular. It might be argued that the word is in fact taken from French rather than Latin; Pasteur used it a good deal and it has survived with his successors more continuously and freely than with us. But this would leave us in the undesirable confusion of having singular and plural spelt the same. There seems, indeed, as Mr. Onions says, no escape for the moment, except to drop the word altogether and think of another one. The progress of thought is always in advance of the progress of language, and the Society for Pure English has a field in the medical sciences which is inherently fertile enough, though whether it will respond very fruitfully to cultivation is another question. The meaning and real utility of such first-rate words as "antigen" become obscured and muddled through misuse, and sympathy may almost be felt with the musical comedy spirit which reduces "bacteriophage" to its final syllable.

A PATHFINDER IN MEDICINE.

Mary Putnam Jacobi was one of the first of the band of women who have taken up medicine as a profession and she met with the opposition from her family which most women pioneers did meet with. The story of her life is told in two volumes[1] which have recently appeared. She was the daughter of George Palmer Putnam and Victorine Haven his wife, George Putnam being a member of the well-known publishing firm. His mother was Catherine Palmer, a sister of whom became Mrs. Peabody, and one of Mrs. Peabody's daughters became the wife of Nathaniel Hawthorne. Mary Putnam was born in 1842 in London to which city her father had come to establish a branch of the publishing firm. The project, however, did not eventuate and the family returned to New York. Mary Putnam had made up her mind to enter the medical profession, but found few facilities in New York for acquiring any medical education, although she was able to take a degree in 1863 from the New York College of Pharmacy. Two years previous to this her father had asked her to postpone her medical studies. Between 1861 and 1863 occurred the Civil War in which George Haven Putnam, Mary's brother, served. He broke down in health and his sister was allowed to go to Brashear City, near New Orleans, to nurse him. On this her father, although still disapproving of her going on with her medical studies, did not withhold his consent. "I am willing," he writes in 1863, "that you should apply them (your abilities) even to the repulsive pursuit (for so it is in spite of oneself) of medical science." After a good deal of difficulty she was allowed to enter as a student of the Paris Faculty of Medicine, and in 1868 she attended the École de Médecine, being the first woman student of that venerable institution. This school, which obtained a separate building for itself in 1281, occupied for a period a house at the corner of the Rue de la Bucherie and the Rue de l'Hôtel Colbert, inaugurated by the anatomist Winslow, who taught there. This was in 1745, but by 1775 the building had got so out of repair that the school moved to the Rue de St. Jean de Beauvais, where Mary Putnam studied. She was admitted a Doctor of the Faculty in 1871, and in the meantime was fortunate enough to meet a number of interesting people, amongst others she became very intimate with the Réclus family. She was in Paris during the siege and the Commune. Her letters throughout her whole stay are bright, witty, and informing, and like a true woman she writes a lot about her clothes. After Paris she returned to New York, where she practised more or less continuously until her death in 1906.

The companion volume contains a carefully edited selection of Mary Jacobi's writings. The earliest of these take the form of letters from Paris to the *New*

---

[1] Life and Letters of Mary Putnam Jacobi. Edited by Ruth Putnam, with a foreword by George Haven Putnam. Mary Putnam Jacobi: A Pathfinder in Medicine. With Selections from her Writings and a complete Bibliography. Edited by The Women's Medical Association of New York City. New York and London: G. P. Putnam's Sons. 1925. Pp. 381–521. 15s. each.

York Medical Record, beginning in 1867, when the writer was 25 years of age, and continuing to 1871, the year of her graduation. For so young a writer they show much accurate observation. One of the most interesting is a précis of a paper read by Mr. Rodet before the Imperial Society of Medicine at Lyons in July, 1867, upon the question of the contagiousness or otherwise of cholera. The meeting apparently came to no conclusion on the matter, but on the question of treatment Dr. Jacobi quotes from Rodet a prescription used by Mr. Lisle, physician at the Marseilles Insane Asylum, which was seriously affected by the epidemic of 1865. It consisted in the administration of copper sulphate. Dr. Jacobi gives the formula, but has unfortunately forgotten to give the dose. Before trying this remedy Rodet lost 12 patients out of 14, but after he began to use it he had 25 recoveries out of 32 cases. The use of copper sulphate has apparently dropped out, but the salt is well known to have a marked power of inhibiting the growth of low vegetable organisms, and a mere trace of it will keep a tank of rainwater free from algæ. Other papers are addresses mainly dealing with women in medicine, such as that reprinted from the *North American Review* for January, 1862. The final paper is pathetic, for it is the account written by herself of the early symptoms of the meningeal tumour compressing the cerebellum, from the effects of which she died. The record begins in 1896 and is continued down to 1903, three years before her death. Sydenham died from an acute attack of gout, a disease from which he had suffered all his life, and his treatise upon which is his chief work; but we have no parallel to a trained medical woman deliberately sitting down to chronicle the progress within herself of a disease which she must have suspected from the first would prove fatal.

OLIGURIA FOLLOWING BLOOD TRANSFUSION.

SETTING aside the avoidable danger of incompatibility, to which Dr. E. L. Hunt called attention last week in our correspondence columns, blood transfusion is only rarely responsible for results which endanger life. F. W. Barcroft[1] has recorded a case of oliguria following transfusion. A woman, aged 49, was rendered anæmic by metrorrhagia due to an incomplete abortion. Prior to curetting she was transfused 400 c.cm. by the Unger method. Tests had shown that there was no agglutination or hæmolysis of the cells of either donor or recipient. The transfusion was followed by a rigor. During the nine days following operation only 35 oz. of urine were secreted. The daily amount varied from 1 to 6 oz. The urine was clear, specific gravity 1010, and contained a trace of albumin. All attempts to increase secretion having failed and the patient's condition being desperate, both kidneys were decapsulated under gas and oxygen, the operation lasting 20 minutes. On the tenth day 9½ oz. were secreted and increased daily, reaching 51 oz. on the fourteenth day. Recovery ensued, but was complicated by a suppurative right parotitis and by a right lumbar intraperitoneal abscess, due to opening and infection of the peritoneum during the hurried decapsulation. Eight cases of extreme oliguria, or anuria, following transfusion are mentioned by Barcroft. Six cases died. Hæmaturia or hæmoglobinuria occurred in several of the cases. In most of the cases preliminary tests had shown compatibility of the bloods of the donor and of the recipient, but in some of the cases tests, performed after occurrence of oliguria, showed incompatibility, there having been errors of technique in the preliminary tests. In one case of pernicious anæmia two transfusions were made from one donor without complications. A week after the second transfusion a third transfusion was performed, this time from another donor. This was followed by anuria for 48 hours. The patient recovered from the anuria, but died of the pernicious anæmia. The bloods of both donors were compatible with the patient's blood, but when the bloods of the two donors were tested against each other hæmolysis occurred. Decapsulation in nephritis, performed by Harrison in 1896 and by Edebohls in 1901, has not been generally adopted. Bessesen, in November, 1924, stated that after decapsulation 65 per cent. improve, 20 to 25 per cent. remain in statu quo, and 5 to 10 per cent. die. He considers that, in nephritis, decapsulation is only of temporary benefit and is a procedure of necessity rather than of choice.

THREE HOSPITAL PHARMACOPŒIAS.

WE have heard it said that the "push-bike" is the piece of machinery approaching nearest to perfection which has yet been invented by man; for whereas formerly there were many varieties, now one type is dominant, and this type has remained constant for many years. On the same principle hospital pharmacopœias must also be approaching perfection, for in outward form they are very similar. Internally they do vary somewhat, but not to any striking extent. In the three examples before us there are, however, a few slips. We note *Sippey* for Sippy, *carbonis* for *carbonatis*, and the students' old error of taking *folia* as singular and declining it *foliæ*, *foliarum*. The London Hospital book opens with some minatory rules, which include the words: "Residents, in their prescribing are confined entirely . . .," on which immediately follows an excellent antidote table. The pharmacopœia itself includes the preparations of the B.P., an arrangement which increases its bulk and its usefulness. A handy summary of the Dangerous Drugs Act is placed at the end of the book, where it is easy to find. The West London Hospital separates its hospital preparations from those of the B.P., giving the latter as a list of doses. The London Temperance Hospital does the same, without giving all those of the larger work. Both of these hospitals go further afield with directions of a general nature. The West London tells how to bring up babies, how to arrange the sanitary condition of the home, and how to give Lenhartz, Sippy, and Graham diets. The Temperance Hospital describes preparation for operation, gives directions for cases of ringworm, and for the management of rickety children. As becomes a Temperance Hospital, there is a note that house surgeons and house physicians must not prescribe brandy and other beverage alcohol on their own responsibility. All three pharmacopœias are as nearly perfect as can be.

SCIENCE AND MISSIONARY WORK.

IN the current issue of the *Journal of the Cambridge University Medical Society* there is an interesting paper by Dr. J. Howard Cook, in which many instances are given of how science has aided the work of missions. Missionary work was from the start a prominent part of the Church's task, and although it did not extend beyond the limits of the Roman Empire during the first five centuries or so of the Christian era, those limits were roughly the limits of the known world, within which disease of all types was rampant. But as early as the sixth century the Nestorian Church pushed as far as Malabar, and by the eighth century China was reached. In the thirteenth century the Orthodox Church of the East had arrived in Persia and the Armenian Church in India, while a little later the Dominicans and Franciscans were at work in Northern Africa. The Jesuit missions of the sixteenth century and after are too well known to need more than mention, and from the seventeenth and eighteenth centuries and onward our own country exhibited active missionary effort. Therefore, for more than 1000 years missionaries have laboured subject to the plagues and pestilences of their centres of work. The records of deaths from disease amongst missionaries are scanty, but there can be no doubt

that disease took a large toll of life from these brave messengers, whose aims in recent days have been furthered by the advance of medicine. Most people welcome a religion if they can obtain some material good from it, and there can be no doubt that the benefits obtained from the cure or prevention of such diseases as malaria, plague, and sleeping sickness have proved, at any rate in primitive eyes, practical testimonials to the value of Christianity. Science has shown the way by which mission hospitals may bring healing to stricken multitudes, and Dr. Cook quotes some striking examples here. In the period 1901–1904 sleeping sickness was responsible for 200,000 deaths in Uganda, the mortality being practically cent. per cent. Missionary work was at first hindered, for the natives said, "Christianity has brought us the sickness." But preventive methods on the lines advocated by Castellani and Bruce were instituted, and the following figures for the kingdom of Buganda show the results: Deaths for 1905, 8003; for 1910, 1527; for 1915, 3; for 1917 and subsequently, none. Such results obtained by Christian teachers naturally disposed the native to a patient hearing. The power that may be obtained by an ethical leader who can cure or prevent disease is dramatic, and modern science is aiding the coming of the time when "all shall be one" in no uncertain manner, not only by disposing the hearts of people to receive Christianity, but also by rendering the lives of devoted workers far more secure than of yore.

"COLDS."

SCIENTIFIC interest in a disease is apt to vary directly with its rarity, so that minor maladies, and in particular the common cold, do not receive that attention in text-books of medicine which their prevalence would appear to warrant. Of recent years the common cold, however, has been studied more assiduously and in particular from the standpoint of prevention. Dr. Leonard Hill and Dr. Argyll Campbell devote a chapter in their new book on "Health and Environment"[1] to the cause and prevention of "colds." They summarise the supposed causes of "colds" under five headings: chills and draughts, certain conditions of the weather, irritation of the respiratory mucous membrane, infection, and bad ventilation. Each of these supposed causes is then discussed in turn. Exposure by itself will not cause "colds" in healthy individuals, as is shown by the immunity to these disorders enjoyed by Arctic explorers and fishermen at sea. If, however, a person is already infected there appears to be some slight derangement of the heat-regulating mechanism, so that he feels a draught of cold air more easily than a normal healthy person and attributes a "cold" already "on him" to this cause. Cold, dry weather and strong drying winds do not favour epidemics of "colds," while unfavourable weather conditions, such as a high relative humidity of the atmosphere with a variable temperature, certainly do. Irritation of the respiratory mucous membrane by dusts and chemical irritants is also a cause of "colds," while a certain section of the community appears to suffer from a nervous derangement of the nasal mucous membrane, so that sudden changes of temperature and atmosphere may produce an acute paroxysm of rhinorrhoea. While "infection is not the whole story," there is no doubt about the importance of this as a cause of the common cold, and such factors as closeness of contact, duration of contact, and general conditions of ventilation vary for this as for other bacterial infections. In the opinion of these two authors, however, bad ventilation is the commonest cause of "colds." Warm, stagnant air produces a congested, swollen appearance in the nasal mucous membrane, which becomes covered with thick secretion and affords a weak spot for bacterial attack. In cool air, on the other hand, the membrane is pale and taut and well moistened with secretion. Added to the hot air so often present in the upper layers of a badly-ventilated room is the occurrence of cold air near the feet. Thus "cool breezes blowing round the head, the radiant heat of the sun, and a warm ground to stand on are the ideal outdoor conditions." The reverse of this which produces cold feet and stuffy heads is said by these authors to be present in the House of Commons! If these elementary facts about ventilation were appreciated a great many "colds" would be prevented. Dr. Russell L. Cecil, in a little popular book on this subject,[2] emphasises this, pointing out that the "non-contagious cold" largely depends upon the condition in which we keep our nasal mucous membranes. Besides dealing with the more common methods of treating "colds," Dr. Cecil describes the chlorine treatment, in which chlorine gas in a concentration of 0·015 mg. per litre of atmospheric air is inhaled by patients either in a special chamber or from an apparatus which delivers this concentration through a paper face-piece. This method, based upon the fact that no cases of influenza occurred amongst the workers in a chlorine plant during the epidemic of 1918, seems to have a certain amount of vogue in America, and Dr. Cecil speaks well of the results. The relationship between influenza and the common cold as suggested by this therapeutic measure is an aspect of "colds" which is especially dealt with in a review of the literature on influenza and the common cold by J. G. Townsend, published by the United States Public Health Service.[3] It is claimed that the association between influenza and minor respiratory disturbances, especially that known as the "common cold," is "more intimate than has been recognised or conceded." The Public Health Service arranged in 1923 to receive fortnightly reports from 10,000 persons in the United States as to whether they had suffered from any of these minor respiratory disorders during the period in question. The final analysis of the material thus collected may help to elucidate the problem.

PORTRAIT OF SIR JOHN MACALISTER.

THE Council of the Royal Society of Medicine has opened a fund to commemorate the 38 years of service of Sir John MacAlister as secretary of the Society. The memorial is to take the form of a portrait or bust to be placed in the Society's house. A letter has been sent to all the fellows and members of the Society. The Council believes that others outside the Society who appreciate the great work done by Sir John MacAlister in amalgamating 18 medical societies into one corporate body will desire to contribute to the portrait fund. Subscriptions should be forwarded to the hon. treasurers, Royal Society of Medicine, at 1, Wimpole-street, London, W. 1. These will be acknowledged in detail in our columns. The first well-supported list accounts for £615.

RETIREMENT OF SIR WILLIAM HAMER.

THE large number of medical men, hygienists, and officials who have come into relations with Sir William Hamer, *Medical Officer of Health to the London County Council*, will learn with sincere regret of his impending retirement. It is 33 years since he became Assistant Medical Officer to the Council under the late Sir Shirley Murphy, succeeding his chief as Principal Medical Officer in 1912. During that long period he has used devotedly his talents as epidemiologist, statistician, and organiser in the public service. He will carry with him into private life the good wishes of all who know the thoroughness and efficiency of his work, and who have experienced the courtesy of his methods.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXIII.

THE TREATMENT OF IRREGULAR TEETH IN ADOLESCENCE.

OUR knowledge of the causes which produce malrelationship of the teeth and jaws is still very imperfect, but that knowledge is slowly increasing, and to the majority of workers in the field of orthodontics it is becoming evident that maldevelopment and lack of coördination of the factors governing growth account for by far the greatest number of malocclusions. The further back these causes are traced the surer becomes the conviction that treatment should be commenced far earlier than at one time was considered necessary.

Preventive Orthodontics.

Many cases are on record whereby successful treatment of the deciduous teeth at 3–6 years of age has rendered further movement of the permanent teeth unnecessary. No cases, so far as I know, have been described where a definite effort has been made so to influence antenatal development that the resulting child has been successfully reared with normal occlusion. Indeed, it would be difficult to prove to the scoffer that careful supervision of antenatal conditions helped to produce a normality which might occur in any case. The fact, however, that malocclusions have occurred even under a most favourable environment would tend to show that mixture of races and inherited tendencies must not be forgotten when considering this problem. Attention should be drawn to the work of Harold Chapman, who, in making an effort to trace the causes of malocclusion, has been studying the teeth and jaws of members of the same families reared under similar or different environment, and other workers are being enlisted to enlarge the scope of this investigation.

One of the causes which leads to a grave complication which intelligent foresight could so easily eliminate is the loss of space in the temporary dentition caused by the reckless extraction of deciduous teeth, and it is surprising that so many operators have so little regard for this important point. It is not to be denied that septic temporary teeth are a specific source of danger to the whole organism and can rarely be treated satisfactorily, but it is reckless prematurely to remove deciduous teeth without restoring lost function and retaining the interproximal space. The dental surgeon who impresses on parents and teachers the value of a healthy deciduous dentition, and carefully conserves those that come under his immediate care, may thus be regarded as a practitioner of preventive orthodontics.

Diet.—The careful preservation of the temporary teeth through the agency of well thought-out diets, attention to general health, and oral hygiene is the ideal to be aimed at, supplemented, if necessary, by simple conservative treatment. For infants breast feeding should be urged, the child's mouth being cleansed after each feed with a soft piece of muslin, wrapped round the little finger and dipped in normal saline solution. The desirable diets for young children have been thoroughly worked out by Sim Wallace and Harry Campbell among others; the reader is referred to their works for more elaborate details and arguments which are beyond the scope of this article. Suffice it to say that the chewing of hard foodstuffs should be arranged and wholemeal bread, crusts, and toast used freely. Most children enjoy biting hard things, and can easily be trained to do so. It will be found that they refuse to swallow lumps of food unless unduly hurried by an impatient nurse. Every meal should end with some form of sweet acid fruit, a little orange-juice, grated apple, or squeezed grapes when the child is very young; as a child gets older the quantity and method of preparation can be varied.

Oral Hygiene.—Sweetmeat eating is a habit forced on children by indulgent parents and relations, and becomes a most pernicious one; some of the most dreadful ravages from caries have been seen to result from giving a child a chocolate "to go to sleep with." The mouth and teeth should always be cleansed most carefully after the last meal at night, which must always be finished with fruit, and nothing at all given after. In the very young probably the cleansing is done most efficiently by training a child to rinse and gargle vigorously with plain cold water or normal saline; antiseptic washes and tooth-pastes should be avoided. Teach a child to use the buccinators from the earliest age, and the tooth-brush, which really needs very skilful use to be efficient, can be eliminated. When used, tooth-brushes should be the smallest made. Most manufacturers make tooth-brushes far too large, and adults would do well to use what are called children's brushes.

When brought up on these methods it will be found that until children go to preparatory schools, where such simple means of preventing dental caries are not appreciated, the deciduous teeth survive their full term of usefulness without a spot of decay, and the jaws are developed within the limits of their inherited possibility. It must not be forgotten that the first permanent molars appear at the age of 6 and ultimately become the oldest inhabitants of the mouth, with the greatest chance of becoming carious. According to the readings of Friel's dynamometer these are the teeth round which centres the greatest masticating stress. The utmost care should therefore be employed in the constant inspection and conservation of these teeth.

Treatment of Established Irregularity.

We are often called upon to give advice in cases where, through ignorance or possibly unfortunate environment, the patient has suffered a loss of growth that can never be restored and the apical base of Franke and Lundström is permanently reduced in size. It is then very doubtful if tooth movement alone will relieve permanently the overcrowded denture. The treatment of children of 13–14 years of age suffering from malocclusion, who have been deprived up to that time of any but the most primitive kind of dental service, is a difficult problem. Dolamore has shown that the most desirable ages for some forms of treatment, for example, when endeavouring to cure excessive overbite by means of a biting plate, are those which correspond to the most active periods of bone growth, that is to say, during the eruption of the first or second permanent molars, and should the latter teeth be late in erupting it may be quite feasible to undertake a line of treatment that would be doomed to failure in a child of more advanced development. It must be recognised that the physiological age of an individual does not necessarily correspond with the actual age. The dental surgeon in England is hampered by the boarding-school system of education, for children are mostly seen infrequently, if at all, during the school term, and dental apparatus of any kind must be so strongly constructed as to withstand a good deal of hard wear without supervision or repair. In this respect girls, who are still sometimes educated at home, have the advantage, and this is fortunate in that parents of girls are, as a rule, more concerned about disfigurement.

Another important practical problem that has to be faced is the length of time that may be involved in a course of treatment. Most authorities agree, although this idea has been a matter of controversy recently, that tooth movement should be slow enough and gentle enough to produce bone growth concurrently with that movement, thereby shortening the period of retention. The prognosis in adolescent cases is always obscure, because it is difficult to study the action and reaction of the different groups of muscles of the masticating face, and to ensure an harmonious

that disease took a large toll of life from these brave messengers, whose aims in recent days have been furthered by the advance of medicine. Most people welcome a religion if they can obtain some material good from it, and there can be no doubt that the benefits obtained from the cure or prevention of such diseases as malaria, plague, and sleeping sickness have proved, at any rate in primitive eyes, practical testimonials to the value of Christianity. Science has shown the way by which mission hospitals may bring healing to stricken multitudes, and Dr. Cook quotes some striking examples here. In the period 1901–1904 sleeping sickness was responsible for 200,000 deaths in Uganda, the mortality being practically cent. per cent. Missionary work was at first hindered, for the natives said, "Christianity has brought us the sickness." But preventive methods on the lines advocated by Castellani and Bruce were instituted, and the following figures for the kingdom of Buganda show the results: Deaths for 1905, 8003; for 1910, 1527; for 1915, 3; for 1917 and subsequently, none. Such results obtained by Christian teachers naturally disposed the native to a patient hearing. The power that may be obtained by an ethical leader who can cure or prevent disease is dramatic, and modern science is aiding the coming of the time when "all shall be one" in no uncertain manner, not only by disposing the hearts of people to receive Christianity, but also by rendering the lives of devoted workers far more secure than of yore.

"COLDS."

Most authorities agree, although this idea has been a matter of controversy recently, that tooth movement should be slow enough and gentle enough to produce bone growth concurrently with that movement, thereby shortening the period of retention. The prognosis in adolescent cases is always obscure, because it is difficult to study the action and reaction of the different groups of muscles of the masticating face, and to ensure an harmonious

that disease took a large toll of life from these brave messengers, whose aims in recent days have been furthered by the advance of medicine. Most people welcome a religion if they can obtain some material good from it, and there can be no doubt that the benefits obtained from the cure or prevention of such diseases as malaria, plague, and sleeping sickness have proved, at any rate in primitive eyes, practical testimonials to the value of Christianity. Science has shown the way by which mission hospitals may bring healing to stricken multitudes, and Dr. Cook quotes some striking examples here. In the period 1901–1904 sleeping sickness was responsible for 200,000 deaths in Uganda, the mortality being practically cent. per cent. Missionary work was at first hindered, for the natives said, "Christianity has brought us the sickness." But preventive methods on the lines advocated by Castellani and Bruce were instituted, and the following figures for the kingdom of Buganda show the results: Deaths for 1905, 8003; for 1910, 1527; for 1915, 3; for 1917 and subsequently, none. Such results obtained by Christian teachers naturally disposed the native to a patient hearing. The power that may be obtained by an ethical leader who can cure or prevent disease is dramatic, and modern science is aiding the coming of the time when "all shall be one" in no uncertain manner, not only by disposing the hearts of people to receive Christianity, but also by rendering the lives of devoted workers far more secure than of yore.

"COLDS."

SCIENTIFIC interest in a disease is apt to vary directly with its rarity, so that minor maladies, and in particular the common cold, do not receive that attention in text-books of medicine which their prevalence would appear to warrant. Of recent years the common cold, however, has been studied more assiduously and in particular from the standpoint of prevention. Dr. Leonard Hill and Dr. Argyll Campbell devote a chapter in their new book on "Health and Environment"[1] to the cause and prevention of "colds." They summarise the supposed causes of "colds" under five headings: chills and draughts, certain conditions of the weather, irritation of the respiratory mucous membrane, infection, and bad ventilation. Each of these supposed causes is then discussed in turn. Exposure by itself will not cause "colds" in healthy individuals, as is shown by the immunity to these disorders enjoyed by Arctic explorers and fishermen at sea. If, however, a person is already infected there appears to be some slight derangement of the heat-regulating mechanism, so that he feels a draught of cold air more easily than a normal healthy person and attributes a "cold" already "on him" to this cause. Cold, dry weather and strong drying winds do not favour epidemics of "colds," while unfavourable weather conditions, such as a high relative humidity of the atmosphere with a variable temperature, certainly do. Irritation of the respiratory mucous membrane by dusts and chemical irritants is also a cause of "colds," while a certain section of the community appears to suffer from a nervous derangement of the nasal mucous membrane, so that sudden changes of temperature and atmosphere may produce an acute paroxysm of rhinorrhœa. While "infection is not the whole story," there is no doubt about the importance of this as a cause of the common cold, and such factors as closeness of contact, duration of contact, and general conditions of ventilation vary for this as for other bacterial infections. In the opinion of these two authors, however, bad ventilation is the commonest cause of "colds." Warm, stagnant air produces a congested, swollen appearance in the nasal mucous membrane, which becomes covered with thick secretion and affords a weak spot for bacterial attack. In cool air, on the other hand, the membrane is pale and taut and well moistened with secretion. Added to the hot air so often present in the upper layers of a badly-ventilated room is the occurrence of cold air near the feet. Thus "cool breezes blowing round the head, the radiant heat of the sun, and a warm ground to stand on are the ideal outdoor conditions." The reverse of this which produces cold feet and stuffy heads is said by these authors to be present in the House of Commons! If these elementary facts about ventilation were appreciated a great many "colds" would be prevented. Dr. Russell L. Cecil, in a little popular book on this subject,[2] emphasises this, pointing out that the "non-contagious cold" largely depends upon the condition in which we keep our nasal mucous membranes. Besides dealing with the more common methods of treating "colds," Dr. Cecil describes the chlorine treatment, in which chlorine gas in a concentration of 0·015 mg. per litre of atmospheric air is inhaled by patients either in a special chamber or from an apparatus which delivers this concentration through a paper face-piece. This method, based upon the fact that no cases of influenza occurred amongst the workers in a chlorine plant during the epidemic of 1918, seems to have a certain amount of vogue in America, and Dr. Cecil speaks well of the results. The relationship between influenza and the common cold as suggested by this therapeutic measure is an aspect of "colds" which is especially dealt with in a review of the literature on influenza and the common cold by J. G. Townsend, published by the United States Public Health Service.[3] It is claimed that the association between influenza and minor respiratory disturbances, especially that known as the "common cold," is "more intimate than has been recognised or conceded." The Public Health Service arranged in 1923 to receive fortnightly reports from 10,000 persons in the United States as to whether they had suffered from any of these minor respiratory disorders during the period in question. The final analysis of the material thus collected may help to elucidate the problem.

PORTRAIT OF SIR JOHN MACALISTER.

THE Council of the Royal Society of Medicine has opened a fund to commemorate the 38 years of service of Sir John MacAlister as secretary of the Society. The memorial is to take the form of a portrait or bust to be placed in the Society's house. A letter has been sent to all the fellows and members of the Society. The Council believes that others outside the Society who appreciate the great work done by Sir John MacAlister in amalgamating 18 medical societies into one corporate body will desire to contribute to the portrait fund. Subscriptions should be forwarded to the hon. treasurers, Royal Society of Medicine, at 1, Wimpole-street, London, W. 1. These will be acknowledged in detail in our columns. The first well-supported list accounts for £615.

RETIREMENT OF SIR WILLIAM HAMER.

THE large number of medical men, hygienists, and officials who have come into relations with Sir William Hamer, Medical Officer of Health to the London County Council, will learn with sincere regret of his impending retirement. It is 33 years since he became Assistant Medical Officer to the Council under the late Sir Shirley Murphy, succeeding his chief as Principal Medical Officer in 1912. During that long period he has used devotedly his talents as epidemiologist, statistician, and organiser in the public service. He will carry with him into private life the good wishes of all who know the thoroughness and efficiency of his work, and who have experienced the courtesy of his methods.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXIII.

THE TREATMENT OF IRREGULAR TEETH IN ADOLESCENCE.

OUR knowledge of the causes which produce malrelationship of the teeth and jaws is still very imperfect, but that knowledge is slowly increasing, and to the majority of workers in the field of orthodontics it is becoming evident that maldevelopment and lack of coördination of the factors governing growth account for by far the greatest number of malocclusions. The further back these causes are traced the surer becomes the conviction that treatment should be commenced far earlier than at one time was considered necessary.

Preventive Orthodontics.

Many cases are on record whereby successful treatment of the *deciduous teeth at 3–6 years of age* has rendered further movement of the permanent teeth unnecessary. No cases, so far as I know, have been described where a definite effort has been made so to influence antenatal development that the resulting child has been successfully reared with normal occlusion. Indeed, it would be difficult to prove to the scoffer that careful supervision of antenatal conditions helped to produce a normality which might occur in any case. The fact, however, that malocclusions have occurred even under a most favourable environment would tend to show that mixture of races and inherited tendencies must not be forgotten when considering this problem. Attention should be drawn to the work of Harold Chapman, who, in making an effort to trace the causes of malocclusion, has been studying the teeth and jaws of members of the same families reared under similar or different environment, and other workers are being enlisted to enlarge the scope of this investigation.

One of the causes which leads to a grave complication *which intelligent foresight* could so easily eliminate is the loss of space in the temporary dentition caused by the *reckless extraction of deciduous teeth*, and it is surprising that so many operators have so little regard for this important point. It is not to be denied that septic temporary teeth are a specific source of danger to the whole organism and can rarely be treated satisfactorily, but it is reckless prematurely to remove deciduous teeth without restoring lost function and retaining the interproximal space. The dental surgeon who impresses on parents and teachers the value of a healthy deciduous dentition, and carefully conserves those that come under his immediate care, may thus be regarded as a practitioner of preventive orthodontics.

Diet.—The careful preservation of the temporary teeth through the agency of well-thought-out diets, attention to general health, and oral hygiene is the ideal to be aimed at, supplemented, *if necessary*, by simple conservative treatment. For infants breast feeding should be urged, the child's mouth being cleansed after *each feed* with a soft piece of muslin, wrapped round the little finger and dipped in normal saline solution. The desirable diets for *young children have been* thoroughly worked out by Sim Wallace and Harry Campbell among others; the reader is referred to their works for more elaborate details and arguments which are beyond the scope of this article. Suffice it to say that the chewing of hard foodstuffs should be arranged and wholemeal bread, crusts, and toast used freely. Most children enjoy biting hard things, and can easily be trained to do so. It will be found that they refuse to swallow lumps of food unless unduly hurried by an impatient nurse. Every meal should end with some form of *sweet* acid fruit, a little orange-juice, grated apple, or squeezed grapes when the child is very young; as a child gets older the quantity and method of preparation can be varied.

Oral Hygiene.—Sweetmeat eating is a habit forced on children by indulgent parents and relations, and becomes a most pernicious one; *some of the most dreadful* ravages from caries have been seen to result from giving a child a chocolate "to go to sleep with." The mouth and teeth should always be cleansed most carefully *after the last meal at night, which must* always be finished with fruit, and nothing at all given after. In the very young probably the cleansing is done most efficiently by training a child to rinse and gargle vigorously with plain cold water or normal saline; antiseptic washes and tooth-pastes should be avoided. Teach a child to use the buccinators from the earliest age, and the tooth-brush, which really needs very skilful use to be efficient, can be eliminated. When used, *tooth-brushes* should be the smallest made. Most manufacturers make tooth-brushes far too large, and adults would do well to use what are called children's brushes.

When brought up on these methods it will be found *that until children go to preparatory schools*, where such simple means of preventing dental caries are not appreciated, the deciduous teeth survive their full term of usefulness without a spot of decay, and the jaws are developed within the limits of their inherited possibility. It must not be *forgotten that the first* permanent molars appear at the age of 6 and ultimately become the oldest inhabitants of the mouth, with the greatest chance of becoming carious. According to the readings of Friel's dynamometer these are the teeth round which centres the greatest masticating stress. The utmost care should therefore be employed in the constant inspection and conservation of these teeth.

Treatment of Established Irregularity.

We are often called upon to give advice in cases where, through ignorance or possibly unfortunate environment, the patient *has suffered a loss of growth* that can never be restored and the apical base of Franke and Lundström is permanently reduced in size. It is then very doubtful if tooth movement alone will relieve permanently the overcrowded denture. The treatment of children of 13–14 *years of age suffering* from malocclusion, who have been deprived up to that time of any but the most primitive kind of dental service, *is a* difficult problem. Dolamore has shown that the most desirable ages for some forms of treatment, for example, when endeavouring to cure excessive overbite by means of a biting plate, are those which correspond to the most active *periods of bone growth, that is* to say, during the eruption of the first or second permanent molars, and should the latter teeth be late in erupting it may be quite feasible to undertake a line of treatment that would be doomed to failure in a child of more advanced development. It must be recognised that the physiological age of an individual does not necessarily correspond with the actual age. The dental surgeon *in England is* hampered by the boarding-school system of education, for children are mostly seen infrequently, if at all, during the school term, and dental *apparatus* of any kind must be so strongly constructed as to withstand a good deal of hard wear without supervision or *repair*. *In this* respect girls, who are still sometimes educated at home, have the advantage, and this is fortunate in that parents of girls are, as a rule, more concerned about disfigurement.

Another important practical problem that has to be faced is the length of time that *may* be involved in a course of treatment. Most authorities agree, although this idea has been a matter of controversy recently, *that tooth movement* should be slow enough and gentle enough to produce bone growth concurrently with that movement, thereby *shortening the period* of retention. The prognosis in adolescent cases *is* always obscure, because it is difficult to study the action and reaction of the different groups of muscles of the masticating face, and to ensure an harmonious coördination between them. If muscle exercisers such as Rogers recommends are used, it is only in exceptional cases that such treatment can be carried out without close supervision. If, for instance, a child is even a partial mouth-breather the group of muscles concerned in closing the mouth is necessarily kept below par for that individual, but muscle exercisers require regular and constant use and make almost impossible demands on an unwatched or unencouraged child. Much may be done in treating the disability of mouth-breathing by the insertion of an "anti-mouthbreathing valve," to be worn at night with the object of re-establishing the habit of nasal breathing after nasal stenosis has been eliminated. Rhinologists often overlook the fact that mouth-breathing persists as a habit even after the nasal airway has been rendered fully patent.

All cases will not, of course, yield to the same treatment. Cases of post-normal occlusion of the mandible with proclination of the incisors are reported successfully treated at the age of 15, and after, without extraction. But, on the other hand, many are known to have reverted that have been treated at a still earlier age. This type of case is often accompanied by a marked "over-bite," the mandibular incisors impinging on the gum behind the cingula of the maxillary incisors. After the second molars have fully erupted it would seem of slight avail to make any attempt to "raise the bite." If the canines are late in erupting and occupy a high position external to the arch the sacrifice of the first upper premolars will often produce a satisfactory result without any supplemental treatment. If at the age 13 to 14 lower incisors are markedly imbricated, showing a developmental lack of bone growth uncomplicated by post- or pre-normal occlusion, the removal of the most lingually placed incisor will often improve the appearance when the attempted retention of all the teeth would involve expansion of both jaws, a long process, and at this age of doubtful utility. Similarly, if second premolars have been allowed to erupt inside or outside the arch, it is doubtful if it is advisable to attempt to regain the lost space and place such teeth in their correct positions in the arch. But there are many cases where the occlusion, which always has to be most carefully studied, will not permit the success of this simple treatment, and misplaced teeth, even after the extraction of others, must be guided into the desired positions with extra mechanical help. Great care should be exercised to make this aid efficient—the mere "wearing of a plate" will not work miracles; any apparatus worn must be designed with intelligence and adjusted with skill. At this age cases of post-normal occlusion of the mandible with proclination of the incisors are probably treated best in this way. Prenormal occlusion of the mandible is usually accompanied by lack of development of the premaxilla, and any treatment undertaken must be accomplished with the additional aid of mechanical appliances.

Although there are many cases of all types that have been treated successfully without extraction at the age-period under discussion, intelligent use of the forceps with or without supplemental treatment would seem to offer the surest means of obtaining a reasonably æsthetic result with far less fear of relapse than any other method.

G. NORTHCROFT, O.B.E., L.D.S., D.D.S.

WOMEN'S HOLIDAY FUND.—For thirty years the Women's Holiday Fund has been engaged in the work of sending away tired women living in the poorer districts of London for a fortnight's holiday at the seaside or in the country. Each applicant contributes something towards her expenses, the average payment made being one-third of the total cost, which is about £2 17s. 0d. for a woman, and £3 7s. 6d. for mother and baby, for two weeks. The committee are making an emergency appeal this year for the sum of £4000–£5000 to purchase a holiday home for mothers and babies, the lease of the one they rented at St. Leonards for this purpose having terminated in 1924. Donations will be gratefully acknowledged by Miss G. Cooper, Secretary, Women's Holiday Fund, 76, Denison House, Vauxhall Bridge-road, S.W. 1.

Special Articles.

SOME GENERAL REFLECTIONS ON PUBLIC HEALTH ADMINISTRATION.

By J. H. L. CUMPSTON, M.D. MELB., D.P.H. LOND.,
DIRECTOR-GENERAL OF HEALTH, COMMONWEALTH OF AUSTRALIA.

III.—THE PRIVATE HEALTH AGENCIES.*

IN view of the trend of evolution in the United States, and, to a certain extent, in other countries and in the international field, it is interesting to examine the significance of some important developments leading towards the displacement of the legally constituted governmental authority from its proper place in control of existing public health activities and at the head of public health progress. Various private agencies have entered into the field of public health and have assumed, especially in the United States, an importance which is, for those who have not seen the conditions, difficult to realise.

There are four classes of unofficial agencies all having an influence on the evolution of public health in the United States more weighty than that of the official Government departments.

(a) The great foundations which have been endowed by wealthy people with large funds for the purpose of promoting the welfare of the community in some way or another, such as the Rockefeller Foundation, Commonwealth Foundation, and others similar.

(b) The various associations and societies which have been formed, such as the National Tuberculosis Association. These are membership societies composed of individuals, interested in some form or another of public health activity who have formed themselves into societies for the promotion of their particular interest.

(c) The American Public Health Association, which has a large membership mostly of persons engaged in some form of public health activity as their professional career.

(d) Agencies which have become interested in public health because of a direct business interest in the success of such work. The most notable of these is the Metropolitan Life Assurance Society, which now spends a very large amount of money annually in public health activities of a very specific and direct nature, on the ground that any improvement in the general standard of public health is financially to the advantage of the company in its life assurance activities.

Range of Private Enterprise.

These agencies are engaged in a wide variety of enterprises, ranging from what are known as demonstration campaigns, through actual field operations, to definite standardisation activities. As examples of these—

(a) The Metropolitan Life Assurance Company was engaged for seven years in a "health and tuberculosis demonstration" campaign at Framingham, the object of which was to demonstrate the principal factors in the spread of tuberculosis and the principal methods for its control, as well as making a general health survey.

(b) The National Tuberculosis Association operates, through its branches, a number of tuberculosis dispensaries, employs many tuberculosis nurses, and carries on similar activities directed towards the control of tuberculosis.

(c) The National Association for Child Hygiene has taken the lead (together with the Metropolitan Life Assurance Co.) in promoting the compilation of a survey of the health status of 83 of the principal cities in the United States.

(d) The American Public Health Association has actually compiled standards for the laboratory examination of milk, water, and sewage which have now been accepted by all official health departments.

The International Health Board stands in a class by itself because of the large amount of its endowment resources and because of its international scope. Notwithstanding its international application it is very closely associated with many activities within the United States—e.g., it subsidises many of the private membership associations, it provides funds for the building of schools of public health in universities, and it provides funds and staff for the inauguration of county health units, operating under the jurisdiction of State health departments. In one State at least an officer of the International Health Board staff is acting as an officer of the State Health Department, being loaned and financed by the International Health Board. It would appear to an outsider that these private agencies in the United States are more active than the official governmental agencies, although perhaps this appearance is due to the receipt by the private agencies of greater publicity. Their exact position in the scheme of public health activities challenges the inquiry of any visitor who goes to study the public health system of the United States.

---

* Parts I. and II. appeared in THE LANCET of July 11th and 25th respectively, and the concluding part will appear in a subsequent issue.

Its Course of Development.

Notwithstanding considerable inquiry it is not easy to gain a clear or comprehensive conception of the conditions which called these agencies into being or an intelligent appreciation of their exact course of development. It would appear, however, that while in some States there has been for many years a strong realisation of the duty of the State Government to establish and maintain a modern health department in accord with the developments in scientific knowledge, in other States there has been a less complete realisation of the responsibilities of the State Government and a corresponding lag in the development of public health activities. In these latter States interested citizens have taken the lead in one or other directions, such, for example, as child welfare, tuberculosis, &c., and by the formation of societies, the enlistment of public interest, and so on, they have supplied the community with the institutions and equipment necessary for the public health, which the governments had failed to provide. This, however, is not the whole story, as these societies have come into being and have become active in States where the necessity for public health activities has been acknowledged by the Governments in practical form. For example, in Massachusetts the public health reform movement in the United States commenced with a vigorous crusade, arising out of the Massachusetts Sanitary Commission in 1850, which led to the introduction of many valuable public health activities and set a standard which has influenced public health development throughout the United States until now. Despite this, there is seen to-day in the city of Boston the interesting development that the city government provides a building, with caretaker and light services, for the housing of certain private societies to which it has, in fact, delegated its responsibility in respect of certain public health functions.

So, throughout the United States, there are seen: tuberculosis being dealt with by the tuberculosis associations; child welfare (including the management of baby clinics) by the child hygiene associations; the actual administration of health responsibilities of the State being delegated by statute to the Alabama State Medical Association; and certain county health departments being staffed by, and partly financed by, the International Health Board. The International Health Board invariably makes it a condition of its coöperation that the State or local community, as the case may be, shall contribute half the cost and agree to, or request, the coöperation.

Criticism of the Private Agencies.

The impression is that there are certain advantages and certain disadvantages attending this complex series of activities, and it would be desirable, in view of developments elsewhere, to consider these.

The advantages, as they were stated, may be summarised as follows:—

1. Private benefactions have provided larger amounts of money for public health than would probably have been available from public taxation.
2. Private agencies feel that they are freer to try experiments, and possibly make failures, than would be a government department.
3. Private agencies can use more unrestrained methods of publicity and public education than can a governmental department.
4. Private agencies reach the ear and sympathy of the public more completely than a government department.
5. By the provision of financial assistance active governmental agencies are enabled to undertake operations which they could not otherwise finance.

The apparent disadvantages may be summarised as follows:—

1. Several agencies in one community are apt to find themselves bidding against each other for (*a*) subscriptions, if in need of funds; (*b*) opportunities to work without competition, if well endowed.
2. If events do not move in the direction the particular agency desires, it is almost inevitable that the agency finds itself (or its officers) committed openly or engaging less obviously in intrigue to induce the Government or the officers of Government to adopt the policy which the agency concerned is advocating.
3. The officers employed by these private agencies or foundations are often persons trained only in a limited field, without any proper training in public health as a whole, and without any experience of public health administration. Public health requires, as an essential for efficiency in its servants, a reasonable appreciation of the whole field of influences which may affect the human individual, and this wide view is not attainable by the system of limited training necessarily adopted by these agencies whose activities are limited by the self-imposed limitations of their field.
4. The abundance of financial resources is in itself an embarrassment. These associations are almost compelled to find means for expending their income, and it has frequently happened that they have inaugurated institutions and campaigns at a rate of expenditure per head of the population concerned which is beyond the normal expenditure-out-of-taxation-revenue capacity of that population. When this has happened either the venture has quietly lapsed or the association or foundation concerned has been obliged to continue the venture out of its own resources.
5. Those associations which are not financially independent find themselves obliged to frame their policies along lines which will assure them of further public financial support and it may be regarded as problematical whether this does not offset the advantage, claimed above, of freedom to try experiments not influenced by political control.
6. It has happened that the associations or foundations have started activities in some communities, either with or without coöperation from the local government, but have found, when they wished to discontinue or to hand over administration to the local people, that the local community was not prepared to assume control; and the initial enthusiasm (sometimes artificial) having evaporated, a permanent result proportionate to the expenditure of energy and money has not been attained.
7. Finally, there is the fundamental objection which is always inseparable from all "easy money." No community can obtain lasting profit from anything which it does not earn by its own efforts. With a community, as with a person, the acceptance of a gift of this kind induces one of two attitudes—either that of the "borrower being servant to the lender," or the care-free laxity of the dependent who finds his needs supplied without any effort of his own. Either attitude is prejudicial to the vigorous growth of any community.

Trend of Events in the U.S.A. and New Zealand.

There are sufficient signs of the trend of events in the United States which should act as sign-posts for the road to be travelled in other countries. The necessity for correlating the activities of the various societies, associations, and foundations has led to the formation of a National Health Council, which represents a kind of group-management of policies without any organic unity. The associations represented on this Council are ten in number. These have now grouped their head offices in the one building, and it is significant that the New York branch office of the United States Public Health Service has its office in the same building and on the same floor as the National Health Council. This Council, or its components, has now associated with itself several persons with actual experience in public health administration as a whole field, in order to provide some approach to a bridge over the gap between these unofficial agencies and the official health machinery. But it is interesting to note that these unofficial bodies are now actively concerning themselves with the establishment of standards for a satisfactory health department for cities of a certain size, and with the formation and promulgation (towards the ultimate object of enforcement) of a mathematical basis of assessment by which the activities of the public health department of any city may be arbitrarily adjudged. In other words, the private membership associations and private foundations feel themselves competent and entitled to compile and promulgate standards by which the work of city health departments shall be adjudged. Inasmuch as this will probably apply in practice only to those cities in receipt, officially or otherwise, of financial assistance from these agencies, there can probably be little objection to those agencies framing standards by which to judge the extent of response to their generosity. But the situation is, in essence, unhealthy. In an educated and self-governing community the measures provided for the people must be such measures as are prompted by the conscious will of the people—i.e., by the Government—or they cannot be permanently successful.

On the other hand, in New Zealand the overwhelming success of the movement for the care of infants has been entirely due to the work of a voluntary society. It was by aligning the women of New Zealand behind his crusade for the protection of infants, and by this means alone, that Sir Truby King was able to secure such striking results. But it has now been found advisable to make a governmental activity of this movement, at least in part, and Dr. King has been joined to the Health Department as an officer of that Department—the whole work being under Health Department jurisdiction.

Government Control or Supervision.

There appears to be a growing opinion amongst these private agencies in the United States that all the work they are doing should properly be part of the work of Government, whichever form or function of government was best adapted to control any particular part of the work, and that the function, if any, of private agencies was to assist governments, not to act as their substitutes. It is impossible to conceive any course of action, other than autocratic governmental prohibition, which would prevent the spontaneous formation of such associations or societies, or prevent some philanthropically-disposed wealthy person bequeathing his money for some purpose of the kind now under discussion.

The State of Alabama has in its legal code an unusual provision :—

> "No board, body, or organisation shall engage in any public health work except under the supervision and control of the State Board of Health."

This method does not entirely prevent trouble. The simplest way to avoid complications arising from this source, a way which would at the same time be most calculated to bring lasting good to the community, would be for Governments, or, rather, the people whom Governments represent, themselves to perform those simple duties in the field of public health which apparently are being left more and more largely to private agencies. Private agencies cannot operate effectively in respect of environmental sanitation which is exclusively a matter for Government. Private agencies find their most profitable and most dramatic field for work in the various phases of individual hygiene, but individual hygiene in almost all its aspects depends for success upon efficient environmental sanitation. The mother, in her relation to public health—i.e., at the time of child-bearing—is influenced by her environment in respect of food, occupation, and infection. The infant at the time when it is the concern of the State—i.e., during the first year of life—is liable to environmental influence in respect of food and infections. The infantile diarrhœas are to a large extent referable to the same environmental factors of sanitation as are the typhoid and cholera group, and are controllable by the same measures as have been used successfully in those diseases. In tuberculosis it is now accepted that environment—i.e., housing, occupation, food (or economic status, which determines all three)—plays a part at least equal in importance to infections. Control of the environment cannot be secured by any haphazard efforts or transient stimulations of public interest by official or unofficial agencies, but must be solidly based upon a legal code deliberately framed by experienced sanitarians and backed by a solid public opinion demanding the enforcement of at least the major provisions.

Public Health Not Purchasable.

One of the most misleading public health epigrams is that officially used by the New York City Health Department—"Public health is purchasable"—as if public health were a tangible commodity. The implication is that with sufficient money the irreducible minimum of mortality- and morbidity-rates can be secured. All experience shows that this is not true. Public health is merely the expression of private individual health which in turn is regulated by the standard of education (upon these matters of health) attained by the individual and the degree to which the knowledge possessed is used. Money will not make a people wise. One can, without surrendering any convictions, welcome gladly the enormous assistance being rendered by these private agencies to the advancement of public health. The International Health Board is, beyond all question, the greatest single force in public health to-day. But, in the end, public health, to be successful, must be the practical expression of the conscious will of the people themselves—which is Government.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Recrudescence of Alcoholism.

DURING the last few years an increase in alcoholism has been noticed in France, which compares unfavourably with the marked diminution of the war period. A commission appointed by the Academy of Medicine has recently been inquiring into this. In his hospital experience during the course of six months, Dr. Achard has found obvious alcoholic stigmata in 44 men out of 418 entrants, and in 38 women out of 579 entrants (roughly 10·5 per cent. of men and 6·3 per cent. of women). This represents only the minimum, for many drinkers did not as yet show any stigmata. Apart from those diseases which had been aggravated by drinking, there were 21 cases—of cirrhosis, delirium tremens, polyneuritis, and gastritis—in which the illness could have been avoided by temperance. Cirrhosis was more frequent amongst women; in 100 alcoholics the proportion of cirrhotics was 18 per cent. for women and 9 per cent. for men. This increase in alcoholism is a reflection of the increase of alcohol consumption in France, which fell from 1.413.000 hectolitres in 1914 to 584.000 in 1918, but has risen again to 1,016,000 hectolitres in 1923 and 968.000 in 1924. The probable causes seem to be: The relative increase of wages amongst manual workers compared with other citizens; the eight-hour day with its increase in leisure; and the reappearance of absinthe in disguised forms. Complete prohibition hardly seems applicable to France, but it would be proper not to give official recognition to fermented drinks as "hygienic," and not to encourage the already excessive production of wine. The use of fresh grape juice, and the employment of alcohol industrially, ought to be developed. The oft-demanded suppression of the privileges of those who distil their own fruit seems an impossibility under the French political system. Some restriction of the number of licences might perhaps be considered, but the electoral power of the wine merchants gives them Parliamentary favour. Private campaigns against alcoholism have only a limited sphere of action. Propaganda should begin in the schools: it cannot be given to adults by their employers because of the distrust which would be excited. The workers' organisations would have more chance of success, and it is their leaders that have to be won over; but perhaps it is the doctor who is most qualified for the task in his rôle of disinterested adviser. It has been suggested that a special commission should be formed under the Commissariat de Santé to undertake a campaign against alcoholism.

Encephalitis and Vaccination against Small-pox.

M. van Bouwdyk Bastiaanse, of The Hague, in collaboration with MM. Bijl and Levaditi, have given an account of their observations on the ætiology of encephalitis in children following vaccination against small-pox. They were concerned with cases which, 10 or 12 days after vaccination, showed signs of encephalitis, characterised by sleepiness, fever, signs of irritation of the pyramidal tract and sometimes paresis, without spinal lymphocytosis. These accidents were noticed during an epidemic of encephalitis. Experiment and pathological research have shown that this form of the disease is not due to the virus of Jenner's vaccine. The various stocks of vaccine used were from a supply obtained from the calf which showed no exceptional neurotropic affinities. There is every reason to suppose that in these cases there was a latent infection by the virus of encephalitis lethargica, and that vaccination merely hatched it out. This agrees with the experience of Levaditi and Nicolau, who have shown that a neurotropic virus can bring out a latent infection due to a different but equally neurotropic virus (e.g., hydrophobia and vaccination). The fact that in the cases under observation the encephalitis developed in a site already affected by the vaccine virus explains the special histo-pathological changes seen.

Insulin in Non-Diabetics.

The trophic action of intramuscular injections of insulin in diabetes is well known. At the time of surgical intervention this substance is capable of hindering the development of toxic accidents; it facilitates the cicatrisation of the operation wound, and diminishes the time required for healing. H. Chabanier has reported a similar trophic action of insulin in the case of atonic wounds in diabetics—e.g., in perforating plantar ulcers and varicose ulcers. This action may also be observed in non-diabetic subjects. In small doses, given by injection, insulin leads to rapid cicatrisation of varicose ulcers in subjects with normal blood-sugar content; but he has employed it by injection and by local application in the form of dressings with an ointment of insulin. In every case the remedy has been well tolerated and a notable improvement observed in the patient's general condition in addition to the local change (modification of the skin in the periphery of the ulcer, which regains its normal supply and rosy aspect). In some cases cicatrisation was rapid. Alone or in combination with general treatment such local applications of insulin are able to render great service to the surgeon.

French Views on Rickets.

In spite of the large amount of work carried out within recent years on the ætiology of rickets, some physicians in France still hold views which they refuse to modify in the light of recent knowledge. Putting aside the opinions of Prof. Marfan, who still maintains the paramount importance of congenital syphilis as a causal factor in the production of rickets, even moderate French opinion by no means accepts, for example, the vitamin theory, although cod-liver oil was first used in France for the cure of this disease. At a recent discussion before the Société Médicale des Hôpitaux de Paris Dr. G. Variot sounded a note of warning on the subject of "sun-deficiency" as an ætiological factor, pointing out that because ultra-violet light had such a striking effect in curing rickets, it by no means followed that deficiency of this light was an important cause of the disease. He then elaborated the theory of "dysalimentation," which stresses incorrect diet at the period of weaning. This remained, in his opinion, the most important factor. He particularly indicted the removal of all milk from the dietary at this period and the substitution of starchy foods made with water. Prof. Comby, who also took part in the discussion, agreed with this view, and, while not denying the importance of hygienic factors such as the sun, air, light, and exercise, stated that these factors did not play any vital part in the majority of cases. He pointed out that in this his opinion had not changed materially since he first affirmed his belief in the alimentary factor 30 years ago; and in a review of the recent literature on this subject published in 1923 he had still maintained that defective feeding, and especially over-feeding, played a most important part in the production of rickets. That both lack of sunlight and defective feeding were closely related causes of rickets was advanced by Dr. Apert, who holds that one of these factors is as necessary as the other; but in reply Dr. Variot disagreed with this. It is noticeable that in the report of this discussion no mention is made of any vitamin, and it is probable that the recent work of Mellanby on the apparent antagonism between excessive starchy foods and the antirachitic factor will be taken here as an additional proof (as, of course, it is) of the dangers of overfeeding with starch during the period of growth. This is an illustration of the way in which facts can be made to bear slightly different interpretations according to prejudice.

The Comparative Action of Atropine and the Total Alkaloids of Belladonna.

Differences in the physiological and therapeutical action of the total alkaloids of a plant and of the essential principle are already well known. P. Lemay and L. Jaloustre have tested the action of atropine and of the total alkaloids of belladonna in the rabbit, and have confirmed the facts already noted by Cushny and Rothlin. The total alkaloids appear to be twice as active as atropine in their action on the cardiac wave, and the authors conclude that there is reason to use them in treatment (especially in spasm and vagotony) in preference to the galenical preparations of the codex. The physician has in them a remedy always of the same composition and twice as active as atropine without being more toxic.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Proposed Alterations in the Medical Curriculum.

A SPECIAL committee appointed by the Ministry of Education, in coöperation with the medical faculty of Vienna and the university boards of the three Austrian universities, has worked out a series of suggestions on the future regulation of medical study in this country. The principal change advocated is the extension of the period of studies. Hitherto ten semesters (five years) have been required; but the medical student will now have to work for a year longer at the university and at the clinics before he can take his diploma of M.D. At the end of his fifth semester (half-year) he will take three minor examinations (biology, chemistry, and physiology) and a severe examination in anatomy; after which he will serve during the next two years as junior assistant in various clinics. Here he will obtain practical instruction at the bedside in the modern technique of investigation, under the guidance of regular assistants of the clinical professors. The final examinations will be held at the end of the eleventh and twelfth semesters, and for both these terms the student will be required to serve in clinics. The "hospital year" for the graduated doctor, which has been adopted in Germany and some other countries, has not found favour here. The committee thinks it advisable that the student should have a year of thorough instruction at the bedside before he is granted a diploma which, according to the law, entitles him to settle down and practise. It has been thought wiser not to alter the fundamental legal regulation. Specialisation by the graduated doctor will also be much more difficult than hitherto. He will only be allowed to style himself "specialist" after having spent at least four years in hospital as interne and assistant after his graduation; and of this period he must have been working for at least three years in the special branch selected. He may then be recognised as "specialist" by the Union of Specialists, which alone is entitled to confer on him this title. It is even contemplated that those present-day specialists who have not obtained a university degree of docent or professor in their special branch should be compelled to pass a (nominal) examination. But this suggestion has met with so much opposition that it will most likely not be enforced.

Insulin Treatment in Cases of Extreme Leanness.

At a recent meeting of the Vienna Medical Society Prof. W. Falta showed several cases in which he had given regular insulin treatment with the intention of obtaining rapid gain in weight. From the very first administration of insulin the appetite was enormously increased, so that the patients were capable of ingesting huge quantities of food. The gain in weight amounted on an average to 1½ kilos per week; and in one case a distinct obesity ensued, so that the treatment had to be interrupted. The absence of œdema indicated that this gain was not a mere accumulation of water. It was, in fact, an apposition of real body substance, as was shown by the presence of layers of fat on the thigh, neck, and abdomen. Only in cases of diabetes was œdema produced by insulin. Prof. Falta pointed out that these observations substantiated his assertions that obesity of a pancreatic (insular) type was very frequent, and that it is probable that insulin—or rather, the organs producing insulin—plays an important part in the mechanism of the regulation of the desire for food. In the ensuing discussion Dr. H. Pollitzer, Dr. Bauer, and Dr. Nyiri reported that they too have observed rapid rise of appetite by insulin treatment. Especially the turgor of the tissues increases rapidly, as water retention without œdema is a practically normal condition which is aimed at in all "feeding up" cures. The insulin treatment must, of course, be conducted in a very careful way, especially in cachectic persons; such individuals are liable to an increased susceptibility to insulin, somewhat similar to that observed in severe cases of diabetes.

Increase of Saturnism in Austria.

Prof. Sternberg recently showed to the Medical Society of this city a woman of 36 years who had suffered for more than eight months from intense headaches, with nausea and frequent vomiting. Mental derangement of the type of a mild mania was also present at times. Slight paresis of the right abducens, a congested fundus in both eyes, and loss of irritability of the vestibular organs were thought to point to a cerebral tumour; but, besides that, a distinct discoloration of the lower lip on its dental aspect, consisting of fine point-like pigmentations typical of plumbism, was discovered. The few teeth present also showed a very distinct but narrow line of the same kind. The history of the patient explained the condition. She was occupied in copying illustrations and drawings for textile fabrics by means of an adhesive dye which contained colophonium, white lead, and soot. The constant use of this mixture had caused a chronic œdema of the brain which produced the symptoms. A course of iodides with intense sweating brought marked relief and the return of normal vision, and all the cerebral symptoms disappeared. In 1836 the name of encephalopathia saturnina was given to this rare variety of plumbism by Tanquerel des Planches. This case gave rise to an extensive investigation in all commercial and industrial enterprises using lead and its derivatives. Especially the use of certain white dyes is fraught with danger, as the workers generally are not aware of the presence of plumbum in them, and are therefore careless. In the discussion fo[illegible] the demonstration, Prof. H. Schlesinger [illegible] that h[illegible] war saturnism had been q[illegible] is[illegible] t that during the last six [illegible] rise in its frequency. [illegible] l electrical workers, it af[illegible] These use coatings containing a fair amount of lead, because lead-containing varnishes give a better finish to the work. Factories seem to neglect the precautions stipulated by the Industrial Labourers' Protection Law, and it is intended to include industrial lead poisoning in the suggested Labourers' Compensation Act as an accident, so that the factories will in their own interest be forced to pay more attention to this point.

Public Health Services.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*

Warrington .	13,117	—†	3,983	4,678	17·8
Stoke-on-Trent..	50,951	—†	14,120	19,887	23·0

* Excluding dental defects and uncleanliness.
—† Not given.

Bristol.

Dr. R. A. Askins, in his dual capacity of school medical officer and deputy medical officer of health, is directly able to maintain the closest coöperation between the medical services of the education and health committees—a matter of great importance in a large community with many health activities. It prevents overlapping and also ensures the continuity of supervision from birth to school-leaving age. The importance of keeping in touch with the child welfare work is exemplified in the special report of the chief assistant school medical officer, Dr. R. R. Garden, on the early rectification of squint by glasses and orthoptic treatment. Seventy-nine children referred by the welfare staff were examined at the clinic; 46 of these were found to be convergent concomitant squints, of whom 12 responded at once by the use of suitable glasses and the others are now under treatment and are mostly improving. As with visual defects so with most incipient abnormalities, early recognition and treatment spells the end of much after-crippling.

Dr. Garden also reports on the outbreak of encephalitis lethargica in 1924. There were 50 cases, of whom eight died. Of the remainder, including a few cases before 1924, 21 appear to have recovered with so far no sequelæ, 19 have more or less severe after-effects—e.g., drowsiness, irritability, lack of concentration, and some loss of control. It is this class which forms a serious educational problem. Institutional care is neither desired nor expedient, yet to return them to an ordinary school, though no doubt advantageous to the individual sufferer, is detrimental to their class mates on account of erratic conduct and partial immunity from punishment. In eight cases the sequelæ—e.g., inversion of the diurnal rhythm, paralysis, intellectual and moral depravity—were so serious that institutional care is urgently required. These figures are comparable with those recently reported among 193 cases in London school-children by Dr. F. C. Shrubsall, and indicate the severity of this new scourge. Not least amongst the disquieting features is the fact that early cases are often missed or lightly treated on account of the mildness of the acute stage.

Dr Askins is happy in reporting on the opening of another new and up-to-date clinic, making the fourth now in operation; in addition, there is an orthopædic clinic where appropriate cases from both the child welfare and school departments are treated or [illegible]ern lines under Mr. Hubert Chitty. Heart cases are all seen by Dr. Carey Coombs and Dr. C. E. K. Herapath, who report in detail to the school medical officer; an excellent arrangement when we remember the highly specialised work of recognising early signs of cardiac involvement and the grave consequences following on untreated early carditis. Special schools exist for mentally and physically defective children. Mr. J. P. Harty, the aural surgeon, states that the numbers requiring admission to the special school for the partially deaf show a definite and steady decrease since the aural clinics were opened. There is an open-air school with accommodation for 140 and three open-air classes are daily held and accommodate 84 children. Since the results of this rational treatment are so good, it is hoped that further facilities will be provided. Deaf-mutes to the number of 55 are treated in a residential school, and special classes are held for myopes and the partially deaf with accommodation for 70 and 40 respectively, and 17 blind children are maintained by the committee at outside institutions.

Warrington.

Dr. G. W. N. Joseph states that the percentage of defects is lower than in any previous year, and a table is given illustrating the influence of infant welfare centres. Among the entrants who had attended these centres the percentage of defects requiring either treatment or observation was 15·3, compared with 27·2 among the other entrants. In other tables he shows how greatly loss of attendance from contagious affections, particularly "dirt" diseases, has been reduced, the days lost in 1922 being 18,227, whereas in 1918 there were 101,453, nearly six times as many. He points out that apart from the other great benefits there is considerable financial gain to the authority by increase of grant. Much credit is due to the school nurses for their preventive and curative work. A special table shows that in ringworm there has been a reduction both in numbers and in time required for treatment, the latter reduction being related to the use of X rays in treatment.

The figures for visual defects during the last four years are set out in detailed comparative tables; they are, on the whole, fairly constant and do not afford evidence of the increase reported in some other areas. As to their treatment we learn from the report that many children were dealt with by "other methods"—i.e., opticians. Many opticians to-day are well trained in general sight-testing and the fitting of glasses, but the strongly acting ciliary muscle of the child makes refraction without a mydriatic liable to error, and examples of the practical evils arising are well known to anyone with acquaintance of ophthalmic practice. A progressive diminution is described in dental defects—i.e., in the percentage of children having four or more carious teeth (a standard which we hope will soon be felt to be too low). On this basis only 0·32 per cent. are called defective, whereas the standard of the dentist gives 75·7 per cent. One expects some difference between the ideal and the practical working scales, but surely this discrepancy is too marked. The proportion of dental cases treated this year (22 per cent.) is low, and the fee scale, which was largely responsible for the falling off, has been relaxed. The dentist thinks that he should inspect less and devote more time to treatment. It is to be hoped that the projected orthopædic centre and the special mentally defective school will soon be in working order. For low grade defectives an occupation centre has been established, but this is badly handicapped by lack of a guide, and such centres are never proper substitutes for special mentally defective schools.

The need for remedy of some gross sanitary defects in the schools is emphasised in this report, the tone of which is otherwise optimistic. In certain other respects the arrangements are as yet scarcely worthy of a town of the importance of Warrington.

Stoke-on-Trent.

Dr. R. Hughes has compiled a voluminous report full of apt quotations and original mathematical tables. Although his interests are wide the consideration of the many topics does not lack thoroughness. He has been unfortunate in the constant changes of staff. No routine inspection has taken place in secondary schools. Dr. Hughes makes some pertinent remarks on the question of overcrowding. He quotes the recommendations of the Council of Ophthalmologists, and agrees with Dr. J. Kerr that progressive myopia is a distinct clinical entity and of great importance. Ionisation of ears is to be started again. Dr. E. A. C. Swainson, assistant school medical officer, remarks on the haphazard treatment which "running ears" usually get.

Stoke-on-Trent is unfortunate in its provision of treatment for enlarged tonsils and adenoids. Out of 1201 cases only 158 received any form of treatment. It has been resolved that the necessary steps be taken to provide for the erection of a school for mentally defective children of the county borough. Dr. Hughes's speculations on the comparative failure of some mentally defective schools are interesting, but his comments on these day schools seem unduly pessimistic. Two special contributions are added—one on the distribution of educational abilities amongmentally defective children has some original features; the other on the relationship of Binet test ages to abilities in individual school subjects is of educational value.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 18TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 00; scarlet fever, 1683; diphtheria, 033; enteric fever, 65; pneumonia, 707; puerperal fever, 38; cerebro-spinal fever, 5; acute poliomyelitis, 4; encephalitis lethargica, 32; dysentery, 6; ophthalmia neonatorum, 131. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, 18 from measles, 8 from scarlet fever, 78 from whooping-cough, 18 from influenza, and 20 from diphtheria. There were 30 deaths of children under 2 years from diarrhœa and enteritis, as compared with 41 and 29 in the preceding weeks. In London itself there were 7 deaths from influenza and 6 from diphtheria.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE ASSOCIATION.—The Fellowship announces that there will be a special series of lectures on tuberculosis from October to December. Beginning on August 24th to Sept. 5th, there will be an intensive course in general medicine, surgery, and the special departments at the Queen Mary's Hospital, Stratford. Sessions will be held each day from 10.30 A.M. to 5.30 P.M., including demonstration of clinical methods, groups of illustrative cases, &c. Special opportunities will be afforded to those desirous of obtaining practical study in gynæcology and obstetrics. The fee for the course is £3 3s., or £2 2s for either week. Courses in progress are: A general vacation course at the Prince of Wales's General Hospital, Tottenham, the fee being £3 3s. or £2 2s. either week, and special courses in nervous diseases and urology at the West End and All Saints' Hospitals respectively. An extensive programme of special courses has been arranged for the month of September. The Seamen's Hospital will give an operative surgery course from Sept. 7th onwards and classes will be held four times weekly. The Brompton Hospital begins a two weeks' course from Sept. 21st to Oct. 3rd, dealing with pulmonary diseases, by members of the staff. There will be an afternoon's course at the Blackfriars Skin Hospital and one at the Infants Hospital, both taking place from Sept. 7th to 10th. At the Royal Westminster Hospital a course in eye diseases will be given from Sept. 7th to 26th embodying instruction in the out-patient department and special lectures and demonstrations on the various branches of ophthalmology. An intensive course at the Westminster Hospital in general medicine, surgery, and the specialties is announced for Sept. 21st to Oct. 3rd. A weekly lecture-demonstration in electrotherapy will be undertaken by Dr. C. B. Heald at the Royal Free Hospital from Sept. 23rd to Oct. 14th. Copies of the syllabus of each of the foregoing courses may be obtained on application to the Secretary at 1, Wimpole-street, W. 1.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

(*Continued from p. 200.*)

REPRESENTATIVE MEETING.

MONDAY AND TUESDAY, JULY 20TH AND 21ST.

Memorandum on Coroners' Law.

THE principal subject occupying the attention of the Representative Meeting on Monday was the Memorandum of the Council dealing with proposed Amendments in the Coroners' Law. The chief alterations it is hoped to bring about are the institution of two forms of certificate of death and stillbirth: (1) Notification of death by natural causes or otherwise, with duration and general nature of the disease, signed by a registered medical practitioner who has viewed the body; if possible by the one who had attended the deceased during life or had been called in at or about the time of death; and (2) a further report on the cause of death containing any scientific data considered necessary or desirable, such report to be private and only open to inspection by a coroner, medical officer of health, or superior police officer. The registrar, in the absence of the first certificate or in cases where it does not strictly follow the statutory form, would notify the coroner.

The discussion centred mainly around the question of the second certificate, whether there should be any reservation on the form issued to the relatives, and if so, what should be done with additional information. Dr. E. W. G. Masterman (Camberwell) argued that double certification involved an extra burden on the practitioner, annoyance to insurance societies, who, as Dr. J. Stevens (Edinburgh) pointed out, would scarcely be willing to meet claims when they knew that a second and confidential certificate had been posted to the registrar, and chagrin of the relatives at not being able to quote the cause of death as certified. Moreover, the scientific value of the second certificate would be small except in cases where a post-mortem examination had been performed or where there was some factor, such as alcohol or venereal disease, which the doctor definitely desired to keep from the knowledge of the relatives. An amendment to delete the line "State disease" on the first certificate was lost on the grounds that this was a concession to the desire of the relatives to have some general disease term given them as cause of death. The supplementary certificate clause was eventually amended on the motion of Dr. E. R. Fothergill (Brighton) and Dr. P. Macdonald (York) to read:

> In addition to the certificate of the fact of death there shall be sent direct to the Registrar-General a further report including further facts as to the cause of death and any scientific data which the practitioner who certifies the death considers necessary or desirable.

Various amendments to modify the suggested fees were thrown out and the remuneration for certification, including viewing the body, was left at the Council's figure of 5s. with additional mileage of 2s.

After a little discussion it was agreed that:

> The Representative Body is of opinion that additional death certificates should not be given except at the request of the patient's representatives or after their consent has been obtained.

Representation on the G.M.C.

The Council recommended:

> That having fully considered the position with regard to the present constitution and the duties and powers of the General Medical Council, the Representative Body does not consider that the Association should take steps (as suggested in Minute 185 of the A.R.M. 1924) with the view of obtaining a larger number of Direct Representatives of registered medical practitioners on the General Medical Council.

This was accepted by 84 votes to 53.

Payment for Health Certificates for Elementary School-Children.

The Representative Body in 1920 agreed that in the event of a school authority requiring a certificate of inability to attend school from a private practitioner the fee for such certificate should be paid by the authority. The Council recommended rescission of this minute as it appeared not to be consonant with the law. The meeting, however, emphasised again their opinion that this state of things ought to be brought about. Mr. Wallace Henry said that in Leicester no medical practitioner gave a certificate to a school-child under any circumstances. The school attendance officer notified the school medical officer if the absent child were seriously ill; if not, he told the parents to take their child up to the doctor for a decision as to whether school attendance was advisable or not. This plan had worked perfectly well. It was the duty of the education authorities to ascertain why a child was absent. The legal position had been known to the Representative Body all along, and in certain areas the education authority did pay, and it ought to in all.

Fees for Examination of Emigrants.

On behalf of the Council Mr. E. B. Turner proposed:

> That the fees chargeable by the medical referees appointed by the Dominions of the Empire to examine proposed emigrants should be as follows: 10s. 6d. for an applicant of 16 years of age or over; 2s. 6d. for each applicant under 16 years, provided their parents or guardians are sailing with them. Not more than two applicants under 16 years of age in one family to be charged for. Applicants under 16 years proceeding alone will be charged 10s. 6d.

This resolution, which was carried, amends the fees adopted in 1923.

Proposed Factory Medical Service.

The proposals of the Council for a Factory Medical Service was discussed, and the following items passed:

> 1. That there should be a distinct department of occupational hygiene attached to the Ministry of Health, which should include the present Factory Medical Service transferred from the Home Office.
>
> 2. That if any changes are made the interests of existing members of the Factory Medical Service should be carefully conserved or compensated.
>
> 3. That as a general rule any practitioner hereafter appointed to perform the duties at present performed by the factory surgeons, or duties analogous thereto, should at the time of appointment be in general practice or have had recent experience of general practice.
>
> 6. That any Factories Bill should provide for due retention of the powers already possessed by local sanitary authorities in respect of factories and workshops.
>
> 7. That so far as practicable all supervision of sanitation in factories, workshops, and workplaces, as defined in the Factories Act of 1901, should not only be retained by the local sanitary authority, but should be extended to all factories.
>
> 8. That any Factories Bill introduced should provide that the Regulations and Orders of the Secretary of State having reference to sanitation in factories, shall apply, local by-laws and regulations notwithstanding, and should be enforceable by the local authorities and not by the Factory Department, except in cases of default.

Paragraphs 4 and 5, dealing with transference of the work to local authorities where possible and the desirability of setting up a complete service of occupational hygiene, were referred back to the Council for further consideration.

Drug Addiction.

Dr. J. W. Bone, the representative of the British Medical Association on the Home Office Drug Addiction Committee, reported the proceedings of a B.M.A. Committee on the subject. The Association sent four witnesses to give evidence before the Home Office Committee—namely, Mr. E. B. Turner, Dr. E. K. Le Fleming, Dr. C. P. Symonds, and Dr. Cox, and Dr. Bone placed before the meeting the provisional findings of the Home Office Committee in order to obtain guidance. An interesting discussion ensued, but as the documents have not yet been placed before the Home Secretary the meeting decided that it would be improper to report the discussion, though useful decisions on the points raised by Dr. Bone were arrived at.

Unqualified Practice.

A motion was brought forward urging amendment of the Medical Acts so that unqualified practice should be illegal, but the meeting decided to pass to the next business.

Nursing Homes Registration Bill.

Dr. E. R. Fothergill, in proposing active opposition to the Nursing Homes Bill, 1925, urged that the Association should refuse support to any Bill that included the following principles: (1) Non-recognition of the local medical profession by the supervising authority; (2) disclosure of private case-records to supervising authority; and (3) inclusion within the definition of a nursing home of premises which are under the control of a registered medical practitioner. To this the meeting agreed, Mr. E. B. Turner pointing out that the original Bill had been withdrawn, as admittedly worded badly, and without doubt the preparation of a new Bill would be preceded by a Select Committee before which the Association would be invited to give evidence.

Remuneration of Assistants.

It was resolved:—

(*a*) That on general principles the employment in suitable cases of assistants by practitioners is in the interests both of the general public and of the profession; (*b*) that it is not desirable for a principal to employ an assistant where he is unable to exercise adequate personal supervision over the latter—e.g., in some types of branch practice; in such circumstances a partnership is to be preferred; (*c*) that the offer or a promise of a future partnership should not be made a reason for paying a lower salary to an assistant; (*d*) that the minimum commencing salary for a newly qualified inexperienced practitioner, acting as a whole-time indoor assistant to a practitioner, should be £210 per annum, with the addition of board and lodging; and in the case of such a practitioner employed on an outdoor basis, the board and lodging value should be estimated from £120 to £160 per annum, according to the circumstances of the individual case; that the only exceptions or possible exceptions to the foregoing should be in the case where, owing to arrangements made for study leave, or to physical disability or other reasons, the assistant is not able to give full time to the work; (*e*) that a whole-time assistant should be entitled to not less than two weeks' holiday a year on full pay.

No steps are to be taken at present to make these resolutions the formal policy of the Association.

Fees at Municipal Maternity Hospitals.

It was proposed by the Chairman of the Medico-Political Committee, and resolved to insert the following paragraphs in the report on the Utilisation of Municipal Hospitals for Civil Needs:—

That where the local authority makes provision for the institutional treatment of maternity cases this should be mainly or primarily for serious cases of antenatal complications, for cases requiring major obstetric operations, for cases where isolation and treatment of septic infection is specially indicated, and other cases where the home conditions are unsuitable or dangerous for confinements.

That where a general practitioner is called upon to render assistance at a confinement in a municipal maternity hospital the fees payable to such practitioner should be in accordance with the scale of fees approved by the Ministry of Health for the payment by local supervising authorities to medical practitioners called in on the advice of midwives, under Section 14 of the Midwives Act, 1918.

That where a consultant is called in by the practitioner in charge of the case the fee for the consultation should be three guineas; that the fee for a major operation should be not less than ten guineas.

Salaries for Public Health Posts.

A good deal of discussion arose on the proposed scale of salaries for public health posts; but the various amendments were lost. The chief difficulty as put forward by Dr. A. T. Jones (North Glamorgan and Brecknock) and Dr. Gordon Bell (Sunderland) was the occupation of junior posts by recently qualified men and women who had had great difficulty in obtaining a situation, and who were submitted to grave hardship and forced to refuse £500 a year offered by county and borough councils. But, as the Chairman of Council pointed out, the scale allowed inexperienced juniors to hold posts at commencing salaries of £500, only demanding that the experience gained by them after their probationary year should be recognised by increased emolument. On the whole, the Association did not wish to encourage the appointment of recently qualified practitioners to public health posts; the scale was intended for those who had had post-graduate experience, often a special diploma, and to whom the local practitioners could look as consulting authorities. Dr. Eustace Hill remarked that many of these posts were blind alleys, as the number of assistants greatly exceeded that of senior medical officers; this must be taken into consideration in assessing the remuneration, as also must the consultant position of these specialists, and the fact that any standard accepted would undoubtedly extend to other branches of medical work. The scale as accepted by the Representative Body is that which appeared on p. 1157 of THE LANCET of May 30th last.

Medical Benevolence.

Some discussion arose on the recommendation of Council to set up a British Medical Association Charities Committee to be constituted and directed according to the following provisions:—

1. The Committee shall consist of the officers of the Association *ex-officio*, three members appointed by the Representative Body and three members appointed by the Council, together with the Editor, the Medical Secretary, and the Financial Secretary.

2. It shall be the duty of the Committee through the machinery of the Association to direct the attention of members to the financial and educational positions which arise as a result of misfortune falling on members of the profession, and to appeal for contributions to meet these positions.

3. All sums obtained in response to such appeals shall be paid to a charities trust fund, the trustees being the members of Council for the time being in office, and shall be distributed to such medical benevolent organisations, and in such amounts as the Committee (subject to the approval of the trustees) shall deem advisable.

4. Contributions paid to the Fund may at the will of the donor either be left to the discretion of the Committee or earmarked for a particular purpose.

Complete unanimity was shown as to the importance and urgency of increasing the support of medical charities, but several members desired that the Association should conduct its own charitable work as the existing bodies were not satisfactorily run. The recommendation of Council was adopted on the appeal of Dr. Bolam, who said that he had had occasion to investigate the working of the Royal Medical Benevolent Fund, and he had found single-minded and devoted officers giving of their energy and often supplementing out of their own pockets the very small sums they were able to distribute; he had been particularly impressed by the work of the Ladies' Guild. The blame was on the profession; these organisations ought to be provided with the sinews of war; he strongly deprecated any assumption of management by the Association, and urged the meeting to help them to get on with the work and to do it cheerfully and freely, for the good of the profession and with no restrictions.

In reply to a question from Dr. Wallace Henry as to the individual voting power of subscribers under the new arrangement, the Chairman said that subscriptions might be earmarked for a certain purpose in which case the individual voting powers would be retained.

Lavatories in Railway Carriages.

It was proposed by Dr. W. Johnson Smyth (Bournemouth), seconded by Mr. Russell Coombe (East Cornwall), and carried without discussion, that the question of the defective ventilation in the lavatories of railway carriages be referred to the Council with power to take any necessary action in the matter.

Whole-time M.O.H.'s.

In proposing a motion—

> That the Representative Body is of opinion that it is inadvisable and improper that whole-time medical officers engaged in public health work should be required to undertake duties other than those for which they were appointed,

Dr. G. G. S. Johnston referred to a bacteriologist required to do post-mortem examinations and a tuberculosis officer required to examine mentally defective children.

The motion was referred to the Council for consideration.

Sale of Vaccine Lymph.

The following motion was brought forward by the Hendon Division:—

> That inasmuch as vaccination against small-pox by means of calf vaccine lymph is the sole obligatory medical operation known to English statute law—abstention being permitted only after statutory exemption has been obtained—calf vaccine lymph be now recognised in the British Pharmacopœia as a therapeutic substance; that standards of purity, potency, and source of seed used in its preparation be prescribed; that the provisions of the Sale of Foods and Drugs Act be made to apply, and that early Parliamentary action be urged to enable the Ministry of Health to lay down and enforce regulations governing the conditions of the preparation and sale of calf vaccine lymph.

This motion also was referred to the Council.

Preservatives in Food.

Dr. Ridley Bailey announced that a Home Office Departmental Committee on Food Preservatives had been assisted by Dr. C. Porter, of Marylebone, and Profs. Dixon and Clark on behalf of the Association. Certain vested interests had put pressure on the Government against the adoption of some recommendations of the Departmental Committee. It was therefore desirable to strengthen the hands of the Government by a strong expression of opinion from the Representative Body. The following recommendations were agreed to:—

> (*a*) That the Representative Body is satisfied from the experiments made, from the recorded cases, and also from the fact that other countries have discontinued their use, that it is essential in the interests of public health that boric acid and boron compounds should not be used as food preservatives.
>
> (*b*) That, whilst recognising that there are difficulties inherent in this country, due to the lack of cold storage facilities and efficient means of transport, which do not exist to the same extent in America and other foreign countries, the Representative Body is of opinion that as a matter of principle it would have been better if the example of other countries in prohibiting entirely the use of preservatives and metallic and other toxic colouring matters in foods could have been followed in the *Draft Regulations re food preservatives*, &c., issued by the Ministry of Health.
>
> (*c*) That the members of the Representative Body draw particular attention to the evils which have arisen in their own experience from the importation of liquid eggs preserved with boric acid, and the Representative Body considers that it is essential from the public health point of view *that liquid eggs preserved* with boric acid or other preservative should be prohibited *at once*.
>
> (*d*) That, subject to the foregoing recommendations, the Representative Body places on record its approval of the Draft Regulations (issued by the Ministry of Health on Feb. 17th, 1925) with regard to preservatives, &c., in food.

Retired Pay of Majors, R.A.M.C.

Sir Richard Luce, Chairman of the Naval and Military Committee, in proposing the adoption of the report of Council under "Naval and Military," drew attention to certain injustices which are present matters of negotiation. Of these the chief concerned the retired pay of majors of the R.A.M.C. This was £1 a day pre-war after 20 years' service, and in 1920 was raised to £396 per annum, but even this was subject to reduction. The War Office was in sympathy with the wishes of the B.M.A. in this matter, but the Treasury had not yet sanctioned the increase which would make their pension proportionate to *that of the rest of the Service*. Another difficulty had been the proposal to raise the age-limit in the Territorial Army, which led to a block in the promotion of majors. In the Navy, the negotiation about the gratuity to senior surgeon-commanders compulsorily retired at the end of the war had resulted in the acceptance of £300 by the officers concerned. The Council of the B.M.A. had suggested that a reconsideration of the pay of junior grades might help to overcome the reluctance of young graduates to enter the R.A.M.C., and the Army had replied that it hoped to lay before the B.M.A. at an early date proposals for the improvement of the conditions of service. After several members had condemned the attitude of the Government in this matter, it was resolved—

> That inasmuch as the provision for a 20 per cent. reduction in retired pay of majors after 20 years' service under the 1919 Warrant can have the effect of reducing the pensions of many of these officers below the sum of £1 per diem which was provided by the Warrant under which they joined the Service, the Representative Body is of opinion that a serious breach of faith has been committed by the *Government, and that, therefore, the Association is unable* to recommend recently-qualified doctors to enter the R.A.M.C., and declines to publish the terms and conditions of service in the R.A.M.C. until the Council is assured that this and other matters under negotiation have been settled to its satisfaction.

Hospital Policy.

Considerable discussion was raised by the proposal of the Council to rescind paragraph 10 of the hospital policy, viz.:—

> *Gratuitous contributions to hospitals* by employers of labour or by employees should not be treated as the payment of premiums for insurance against the cost of maintenance and medical treatment for sickness or accident, nor as entitling the contributors to claim hospital treatment, either for themselves or for persons nominated by them, but as charitable contributions to be expended at the discretion of those to whom the management of the hospital is entrusted.

Several members, including Dr. Peter Macdonald (York), Dr. F. Radcliffe (Oldham), Dr. R. D. Mothersole (Bolton), and Dr. J. M. Mitchell (West Bromwich) spoke to the motion, and the *provincial* members held that the hospital policy as proposed by Mr. H. S. Souttar, Chairman of the Hospital Committee, was not adapted to the conditions of midland and northern hospitals. Nevertheless, the motion of Council was passed by the requisite two-thirds majority, as was also the following new paragraph:—

> 9. Contributions to hospitals by employers of labour or massed or periodical contributions by employees should be considered as contributions for services rendered or to be rendered.

Dr. A. P. Thomson (Birmingham) proposed:—

> That taking into consideration the importance of medical education and the fact that the large teaching hospitals are specially organised and staffed for such work, this meeting is of the opinion that in the scheme of hospital policy of the British Medical Association these hospitals should be put in a class by themselves.

This was referred to the *Council for* consideration, and it was further agreed:—

> That in all cases of accident where medical attendance is given at a voluntary hospital, and such medical attendance is covered either directly or indirectly by insurance, the hospital authorities should recover from the insurance company the full cost of maintenance and treatment of such patient; that where patients who would ordinarily be considered as private patients are admitted to hospital solely on account of accident or emergency they should be considered as "private patients"; and that case-sheets and records of patients treated in hospitals should remain in the custody of the hospital: that they must be regarded as confidential documents and access to them allowed solely to the members of the visiting staff of the hospital.

During the course of the meeting Dr. Brackenbury was elected unopposed to the chair of the Representative Body, and Dr. C. O. Hawthorne was elected deputy chairman.

ANNUAL GENERAL MEETING.

Tuesday, July 21st.

The Annual General Meeting was held in the Concert Hall of the Pump Room on Tuesday, July 21st, when the outgoing President, Mr. J. Basil Hall, inducted Mr. W. G. Mumford as acting President during the illness of the President, Dr. F. G. Thomson.

The report of the Representative Body that Mr. R. G. Hogarth had been elected President for 1926–7 was received, and Mr. Hogarth extended to the Association a warm welcome to Nottingham next year.

Dr. R. A. Bolam, in proposing a vote of thanks to the past President, pointed out that he was the first President of the Association to visit America as an official delegate. Mr. Basil Hall expressed his enjoyment of his visits to the United States and Canada and the pleasure it had given him to occupy the presidential chair in such an active and interesting year. The meeting then adjourned until 7.45 P.M., when Mr. W. G. Mumford took the chair in the Palace Theatre. He was supported on the platform by the Marquis of Bath, Lord High Sheriff of the County of Somerset; Alderman Cedric Chivers, Mayor of Bath; Madame Sarah Grand, Mayoress of Bath; the Venerable Archdeacon of Bath; Mrs. Thomson, Mrs. Mumford, the past President, the President-elect, many members of Council, and the chief officials of the Association. Dr. R. G. Gordon, honorary local general secretary, introduced the two new Canadian Vice-Presidents and several distinguished foreign guests and overseas delegates. The Middlemore prize, consisting of an illuminated certificate and a cheque for £50, was then presented to Mr. Basil Graves in recognition of the contribution he has made to the microscopy of the living eye, especially in relation to the use of the slit-lamp. The gold medal of the Association, for distinguished services, was presented, amidst loud applause, to Dr. R. A. Bolam, chairman of the Council since 1920. Mr. Basil Hall, in introducing him, said that the engrossed testimonial set out many of his qualities and invaluable services, for which all were deeply grateful. His family motto should be "Service, not Self."

The Presidential Address, which appeared in last week's issue of THE LANCET, was then read by the President's son, Mr. Malcolm Thomson, and illustrated by lantern slides. A vote of thanks to the President was moved by Dr. Brackenbury and seconded by the Archdeacon of Bath, both of whom expressed the general admiration of the ability and grace with which it had been delivered. After a vote of thanks to Mr. Mumford, the company were received by Mrs. Thomson and Mr. Malcolm Thomson in the historic Assembly Rooms, where they enjoyed a pleasant social evening.

ANNUAL DINNER.

The annual dinner was held in the Assembly Rooms on July 23rd. Lord Dawson, in proposing the toast "Our Hosts," spoke of the beauty and hospitality of the city of Bath, and referred with particular appreciation to the part played by the Mayor in providing such lavish entertainment. Alderman Cedric Chivers, 695th mayor of the city, agreed with all Lord Dawson had said about Bath and its citizens, adding that the only exaggeration was contained in the reference to himself. The Marquis of Bath proposed "The B.M.A.," remarking on the pleasure it gave him, a layman, to wish the doctors the best of health. Dr. Bolam, replying, spoke of the attitude taken by the B.M.A. with regard to such questions as unqualified practice; he said that the Association must always stand for the interests of the community and must not interfere with the undoubted right of the head of every household to try his hand at healing his own relatives. Sir StClair Thomson proposing "Our Guests" gave a message of welcome from his kinsman the President. This toast was replied to by Dr. A. J. Orenstein (Johannesburg) and by Dr. W. D. Haggard (president of the American Medical Society). The presentation of the golfing cups by Mrs. Thomson followed. The Ulster cup was won by Dr. G. Brand of Glasgow, and the Childe cup by Dr. W. V. Wood of Yatton. "The President" was proposed by Dr. Brackenbury, who wished Dr. Thomson an early restoration to health, and thanked the acting President, Mr. Mumford, for the way in which he had risen to the occasion in particularly difficult circumstances. Mr. Mumford responded.

EXCURSIONS AND SOCIAL AMENITIES.

The Representative Body were taken by motor charabancs to Stonehenge on Sunday, July 19th, where they were met by Dr. J. P. Williams-Freeman, of Andover, who gave a most interesting and instructive lecture about the monument. An exceptionally large number of excursions and conducted tours were arranged during the week, and visitors were given every opportunity to see the baths and other interesting features of the town and its very beautiful environs.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JULY 22ND.

Filter-Passing Viruses.

It had been arranged that the discussion on filter-passing viruses at this section should be opened by Dr. W. E. Gye, and after some preliminary words of welcome from Prof. J. C. G. Ledingham, President of the section, Dr. Gye was called upon. He began by explaining that it had been his original intention to speak on the general question of filter-passing viruses, and that he had actually composed a paper on this subject, but that he had since been requested to speak on his special research into filter-passing organisms found in cancer because of the widespread interest aroused by his article in THE LANCET of July 18th. He left it to the meeting to decide on which subject he should speak. Cancer was demanded with a unanimous voice, and Dr. Gye put aside his paper on filter-passing viruses and spoke for 20 minutes on his recent researches.

Up till recently, he said, we have been satisfied with the general conception that in order that disease may occur it is sufficient to bring together host and parasite. Though this holds good for many contagious diseases, it breaks down when applied to many bacterial diseases, particularly those due to anaerobic bacteria. Thus the tetanus bacillus, washed free from toxin, becomes harmless to laboratory animals. A mouse is not made ill by tetanus bacilli alone, but is killed by those germs if at the time of inoculation some tetanus toxin be also present. Although less clearly established, there is much to suggest that a similar third factor exists for diseases other than anaerobic infections. For example, 10 per cent. of the inhabitants of this country carry the cysts of amœbic dysentery; yet no epidemic occurs. We do not know the conditions which determine the onset of amœbic dysentery. Clearly the conjunction of host and parasite is not sufficient to cause it. An equally suggestive field for speculation is provided by cerebrospinal fever. During war-time outbreaks of this disease it was sometimes found that 50 per cent. of contacts harboured the specific germ yet remained well.

Dr. Gye then turned to the question of the specificity of malignant tumours. It is known that all species of animal are liable to cancers, yet hitherto cancers have only been successfully passed from one animal to another of the same species, and only by the medium of living cancer cells. Thus a tumour arising in a mouse may be transmitted by living cells to another mouse, but not to a rat. This strict specificity has always appealed to the pathologist as an almost incontrovertible argument against the hypothesis of a living agent as the cause of cancer; yet there remained one experience, an apparent exception, which forbade the dismissal of the germ theory of cancer. In 1911 Peyton Rous discovered that the filtrate from a chicken sarcoma tumour would produce sarcoma in fowls of the same breed. This was the first definite evidence of malignant tumours being transferred by other means than the injection of malignant tumour cells, but two other tumours were subsequently described which could be handled in a similar way. These three tumours differed radically in their characters. Thus the first was an embryonic type of sarcoma, the second an osteo-chondro-sarcoma (changed, by passage, from a benign to a malignant growth), and the third was a spindle-celled sarcoma with peculiar rifts running through it. All these could be diluted with saline and filtered, yielding an infective filtrate—but this was infective only for birds of the same species. The active filtrate always produced a tumour of the same character as that from which the filtrate was derived, and this specificity forced the conclusion that each type of tumour sprang from a separate type or species of virus. In defending other manifestations of cancer from the germ theory, orthodox pathologists argued that this strict specificity necessitated the postulation of a separate virus for every type of animal or plant tumour, an argument which seemed to reduce the germ theory to an absurdity.

Turning now to his own work, Dr. Gye gave a brief account of his recent researches. He described the method he had discovered for separating the filtrate of a chicken sarcoma into two fractions, each inactive without the other, but causing a malignant growth when both were injected. Thus by spinning the filtrate at about 9000 revolutions per minute, and washing the deposit obtained, he supplied himself with two fractions, a washed deposit and supernatant fluid. Neither of these would cause sarcoma by itself, but they were infallibly active when combined. This experiment, he declared, he had repeated many times, and he has come to look upon it as a key to the understanding of tumours. The next stage of his research was the production of tumours in mammals with cell-free filtrates. Previously this had not been accomplished for rat and mouse sarcomas; but Dr. Gye found that a tube of culture-media to which a piece of one of these tumours was added, possessed, after filtration, the capacity for inducing malignant growth. This proved that mammalian tumours do not differ essentially from the tumours of birds described by Rous. He was able to show finally that the same principles hold for mammalian tumours as for sarcomas of birds, and that two separate elements are necessary for the successful transmission of the tumour—(1) the living virus, and (2) the specific substance derived from the parent tumour.

Dr. Gye was followed by Mr. J. E. Barnard, who spoke on the microscopical examination of filterable viruses. Our readers have recently had the opportunity of studying the masterly exposition by Mr. Barnard on this subject (The Lancet, July 18th), and his remarks at Bath covered the same ground as this paper.

Dr. M. H. Gordon pointed out that there are two obvious criteria wherewith we can differentiate viruses—namely, (1) their highly specialised pathogenicity, and (2) their specific immunising action Three years ago he had submitted a paper to this section of the B.M.A. meeting at Glasgow on the influenza virus, but owing to lack of material, ignorance of how to handle the virus. and the difficulty of recognising the disease in the inoculated animal. he had abandoned this study and resorted to a humbler virus, a supply of which was always available—namely, vaccinia. For the last three years he has been studying this virus by the experimental method and the results have been embodied in a report to the Medical Research Council which is now in the press. Dr. Gordon showed a number of lantern slides illustrating the methods used in this research and some of the results obtained. The main conclusions to which this work has led are, first, that both vaccinia and variola viruses are particulate and largely retained by the Berkefeld filter. He declared that the presence and abundance of the virus can be measured, within limits, by the quantitative virulence test and by such serological methods as complement fixation and agglutination. He has satisfied himself that active immunity can be produced to vaccinia with either attenuated or killed virus provided the dose is sufficient. He reported some remarkable instances of the capacity of vaccinia to excite acute nasal catarrh. He noticed that the flocculi deposited from suspensions of vaccinia or variola virus by specific agglutination are composed of spheroidal bodies closely resembling those Mr. Barnard found in cancer cultures. Similar bodies have been found in flocculi from precipitin reactions. Further investigation along this line was not made, the immunity and serological questions being the chief preoccupation of Dr. Gordon's research.

Dr. Gordon was followed by Dr. J. E. McCartney, who began by saying that Dr. Gye was fortunate in having selected for study a tumour that could be examined under experimental conditions in its proper host. To learn more of the nature of filter-passing viruses we must turn to the simplest and those most easily studied, such, for instance, as the virus of mosaic disease of tobacco and tomatoes. The difficulties of work with human virus diseases was exemplified in his own experience with influenza, measles, common colds, and febrile herpes. All these diseases, not being natural infections of laboratory animals, offer perplexing difficulties, and it often remains extremely difficult to say with certainty whether or not the disease has been transmitted. Dr. McCartney explained the failure of the filtration of brain tissue from rabbits dead from herpetic encephalitis as being due to the fact that the lipoid material from the brain is in a state of colloidal suspension, and the pores of the filter become clogged with it. If, however, a small piece of the infected brain be placed in a tube of 2 per cent. glucose broth and incubated for 48 hours at 37° C., the virus passes out of the brain tissue into the surrounding broth, which, if filtered through a Berkefeld filter, is found to have retained its infective power. Dr. McCartney was emphatic that cloudiness in Smith-Noguchi medium does not necessarily mean virus growth, as this is frequently seen in sterile uninoculated control tubes. Smith-Noguchi medium, except for the growth of "globoid bodies" of poliomyelitis and *Bacterium pneumosintes*, is unsuitable for the cultivation of filterable viruses. The granules seen in stained films from cultures are not the actual virus. Animal experiment is the only reliable test for the presence of filterable viruses, but in this work the importance of adequate controls cannot be overestimated, as proved by a recent experience in which a virus disease appeared in experimental animals, a virus which was not ætiologically connected with the disease being studied.

Discussion.

At the conclusion of Dr. McCartney's paper a discussion took place, in which the following took part: Dr. J. A. Arkwright, Dr. M. Coplans, Dr. R. P. Garrow, Prof. Ledingham, Dr. Manson, Dr. J. Menton, Dr. Pybus, and Dr. Stephens.

At the President's suggestion the discussion was conducted in an informal fashion, and, for the most part, it took the form of questions which were addressed to either Dr. Gye or Mr. Barnard or Dr. Gordon. Neither Dr. Gye nor Mr. Barnard could be persuaded to go beyond their written word. Dr. Gordon and Prof. Ledingham both spoke on their recent researches on vaccinia. Dr. Coplans spoke of the differences which exist between different filters and pointed out many possible fallacies in filtration experiments.

SECTION OF MEDICAL SOCIOLOGY.

FRIDAY, JULY 24TH.,

Standardisation and Purity of Milk.

This section, under the presidency of Dr. C. E. S. Flemming, devoted two sessions on July 24th to the subject of milk-supply. The morning discussion was opened by Dr. R. Stenhouse Williams, of the Reading Institute, who said that the educational effect of the examination of milk might in time largely obviate its necessity as a control; for its own good the industry would offer only the best to the consumer. Bacteriological standards for cleanliness of milk were only introduced into England in 1917. At that time sufficient work had been done to justify a tentative standard for Certified milk of 30,000 per cubic centimetre and the absence of *B. coli* in two out of three tubes of one-tenth of a cubic centimetre. In New York the numerical standard was 10,000, and there was no standard for *B. coli*; he thought that the English standard, by the inclusion of the *B. coli* test, was a better means of controlling methods of cleanliness. As time progressed, and with the introduction of the Dairies Act of 1922, it had become possible to lay down further standards for different grades. The *B. coli* test did not apply to pasteurised milk. Dr. Williams then gave a series of results obtained at different periods of the year. These showed that it was possible to maintain the Ministry's standard for Certified milk, and that clean production depended not so much on the buildings and equipment as upon the skill of the workers and the unflagging interest of the farmer or milk dealer. The Ministry of Agriculture had done much to create this skill and interest—by demonstrations at cattle shows, by the distribution of literature, and, most of all, by the ever-increasing number of clean-milk competitions. In arranging these competitions it was desirable that they should continue for a long period—e.g., six or twelve months—so that a new habit of mind would have time to develop. Results hitherto obtained had shown the great value of bacteriological examination, by which alone it was possible to rescue the work from a fog of talk. The Ministry of Agriculture was encouraging agricultural colleges and county educational authorities to appoint agricultural organisers, who would not only carry out bacteriological tests but would go down to the cowsheds and the premises of the dairymen to study the conditions under which the work was done. Several such appointments had already been made.

Dr. W. G. Savage (county M.O.H., Somerset) said that the public health administrator made four demands on milk supplied: (1) That it shall not transmit infectious diseases; (2) that its nutritive qualities shall be maintained; (3) that no chemicals shall be added to it to the prejudice of the consumer; (4) that its price shall be as low as practicable after the above three postulates have been satisfied, so as to be readily available for the community. The third demand had been already met by the legislature. He thought that bacteriological standards should be used as a help to the trade and for picking out the worst cases. He was not yet in favour of a fixed bacteriological standard, non-compliance with which should be a punishable offence—the method adopted in the U.S.A. As regards the nutritive quality, it was well known that the average fat-content of milk, as judged by the examination of samples, was about 3·0; whereas the presumptive standard was only 3 per cent. If the presumptive standard were made a legal one, it would be unfair to the smaller purveyors and producers. The big companies with skilled staffs and working with large quantities of milk would be able to reduce their milk to the standard to a nicety; whereas the small man would be unable to hit the happy mean between a profitable abstraction of fat and an excessive but illegal removal. Milk producers who delivered milk below the standard should receive prompt notice, and the mixed milk of the herd should be sampled before any question of prosecution arose. Dr. Savage also considered that reasonable methods should be gradually introduced for keeping up the vitamin content of the milk. If we freed ourselves from the demands of extremists, there was nothing to prevent the milk-supply being rendered safe without an appreciable increase in cost. The Committee on Milk Production had pointed out eight ways in which cost might be lowered, one of which was the elimination of unprofitable cows by means of milk recording. Undoubtedly the cost of the supervision of the milk-supply would be increased by the new proposals. This, however, would not fall upon the milk trade, but rather on the general public health expenses of the country, and therefore it would not affect the price of milk.

Dr. Eric Pritchard spoke from the point of view of the clinician. Although milk was such a valuable food that any attempt by legislative or other means to attain Utopian ideals of cleanliness, irrespective of cost, would be little less than a national calamity, it was at the same time without question the most dangerous vehicle for the conveyance of infectious disease. Experience in this country and in the U.S.A. had shown that the commercial production of a raw milk, which is safe from this point of view, is an impracticable proposition. Complete safety could only be obtained from milk rendered sterile immediately before consumption. If we were prepared to dispense with absolute safety and to accept relative safety, the only solution was the commercial pasteurisation of the whole milk-supply. The old bogy that the nutritive qualities of milk were seriously prejudiced by the process of pasteurisation had, he hoped, been finally disposed of. For his part he was well satisfied with the standard required under the Milk Designation Order (1923), provided that the pasteurisation of all milk not reaching the Grade A standard was made obligatory.

Discussion.

Mr. Wilfred Buckley (National Clean Milk Society) stated that if cows got sufficient food it was impossible to increase the fat-content of the milk by choice of food. He did not see how the vitamin-content could be kept up during the winter. In his herd of about 80 cows the milk frequently contained less than 3 per cent. of fat, although the average was well up to 3·0 per cent. He did not believe that the practice of "toning" down the milk was in operation. Mr. Quinton (sanitary inspector, Liverpool) spoke in favour of the value of methods as contrasted with structures for producing milk with a low bacterial count. He believed that "toning" was practised. Mr. Ben Davis (United Dairies) said the home was the worst source of contamination. There was no "toning" of milk. The records of his company showed a progressive improvement in the cleanliness of milk supplied to it, as shown by bacterial count. Mr. J. C. Coleman, M.R.C.V.S. (Swindon), drew attention to the high charges made for the distribution of milk and to the impossibility of cleaning milk once dirtied. Mr. Tusting (lecturer to the United Dairies Co.) said he had leave to refer to an experiment recently carried out by the Medical Research Council showing the great improvement in school-children resulting from the addition of extra milk to their diet, and the fact that there was no deterioration in properly pasteurised milk. The report would be published in the autumn. Chicago was now supplied with 98 per cent. pasteurised and 2 per cent. Certified milk.—Mr. S. R. Whitley (British Dairy Farmers' Association) appealed to the doctors to say "Drink more milk."—Dr. H. Scurfield agreed that we should drink more milk; but in order to achieve that object the doctors must be convinced that the milk was safe. The protection of milk in the home was not the subject for discussion. The suggestion that the milk was contaminated in the home was no excuse for the delivery by the trader of contaminated milk.

Dr. Stenhouse Williams and Dr. Savage replied. Dr. Savage did not think, from his experience in Somerset, that distributing companies made any effort to encourage the farmers who supplied them with milk to deliver it in a clean state. He still thought that "toning" was practised.

The morning session concluded with the exhibition of two films showing methods of clean-milk production on the farm, and of pasteurisation on a big scale.

Milk-supply and Cost.

During the afternoon the section continued the discussion on milk-supply and cost. Mr. Wilfred Buckley spoke from the producer's standpoint. It was for various reasons at present impossible for the majority of farmers to maintain tubercle-free herds. Mainly by the Government's efforts the number of tubercle-free herds had increased from two or three to upwards of 250; but tubercle-free milk was unlikely to become general in this generation's life-time. Decent cleanliness was, however, practicable, and by coöperation the entire milk-supply could be raised to Grade A standard. The public should be educated to require this standard. He estimated that clean methods on the part of the dairy-farmer cost about ⅜*d.* per gallon and that the sterilisation of apparatus cost about ¼*d.* per gallon, and that a further expenditure of 2*d.* per gallon was necessary to maintain a tubercle-free herd. Mr. Buckley made a strong protest against the doctrine of Dr. Clive Riviere, expressed at the recent Tuberculosis Conference in London, that raw cow's milk should be given to infants in the hope that it contained a few bovine tubercle bacilli and might therefore produce a certain immunity against the human bacillus. Ordinary raw milk might contain no tubercle bacilli, or it might contain an excessive dose. Such a proposal was therefore quite unscientific.

Mr. George P. Male, M.R.C.V.S. (Reading), speaking as a veterinary surgeon, said that he was satisfied that the use of the tuberculin test, together with proper facilities for isolating reactors and for the breeding and rearing of non-tuberculous young stock, could be relied upon to secure a healthy herd within a reasonable time. It was much to be hoped that the Medical Research Council would be able to evolve a test which would be less expensive for the owner. The number of reactors found in a herd might vary from 5 per cent. to 90 per cent. It was a sound economic proposition to make a herd tubercle-free for many reasons. (1) The loss from wasters may amount to £300 a year in a herd of 50 cows. (2) Tubercle-free cows hardly ever need the help of a veterinary surgeon. (3) The average life of a tubercle-free cow is longer. (4) Cows suffering from a wasting disease like tuberculosis are more expensive to feed. (5) In the case of pedigree herds animals cannot be sold to foreign buyers unless they pass the test. (6) When a cow is tuberculous, sooner or later tubercle bacilli will find their way into the milk. When this occurs the owner will have to take steps to find the offending cow or cows. He may have his milk banned, or, under the new Act, he may be fined or lose his licence. (7) There is a ready sale at enhanced price for young stock from tubercle-free herds. (8) When sold to the butcher there will be no loss for subsequent condemnation. The public was now beginning to realise the value of clean milk from healthy cows and to be prepared to pay for it. Mr. Male believed that the production of Grade A tuberculin-tested milk cost the producer less than 3*d.* per gallon extra, and there was no reason why this milk should not be used by all. The producer, however, was waiting for a market, and the distributor for an assured supply. If medical men throughout the country recommended this class of milk, the whole of the milk-supply would be revolutionised.

Mr. J. H. Maggs (chairman of the United Dairies Co.) said that the volume of milk from tuberculin-tested cows was not likely within this generation to exceed a small percentage of the whole. He hoped something would come from the Spahlinger method of immunisation. He thought the reintroduction of the Tuberculosis Order would involve a sheer waste of public money. The sheet anchor of the distributors would for long be pasteurisation. He thought they should go slow with the idea of a maximum count; but that, as time went on, they would be able to lower the counts and make the examination more stringent.

Prof. Walker Hall (pathologist, Bristol Infirmary) said the Government standards were tentative, and could be tightened up gradually. Patient education of the staffs engaged in the milk trade was necessary. Progress had been slow in Bristol during the last 16 years, but more rapid recently. They must help rather than prosecute the farmer.—Mr. Cumber (farmer, Reading) believed that bovine tuberculosis could be eradicated in 20 years. A penny per gallon would pay for clean milk methods and 2*d.* per gallon for the added cost of maintaining tubercle-free herds.—Mr. Boutflour (agricultural organiser, Wiltshire) spoke on the great educative value of clean-milk competitions. The large proportion of reactors so frequently found in a herd was a legacy from past days of over-milking, bad feeding, and bad housing.—Mr. J. R. Catmar, M.R.C.V.S. (Abingdon), said there was very little clean milk and that much was still produced under appalling conditions.—Mr. Quinton testified that the Tuberculosis Order of 1914 was a valuable measure during the period when it was in operation.—Mr. Coleman said that tuberculin testing was often inefficiently done. Also there was the difficulty caused by doping.

Conclusions.

The speaking clearly indicated the variety of interests represented, which included the National Farmers' Union, the British Dairy Farmers Association, the Sanitary Inspectors Association, the United Dairies Ltd., and the Association of Women Sanitary Inspectors and Health Visitors. To anyone who had attended the milk conferences held in this country during the past four or five years it is obvious that some progress towards a better supply has been made, and that the Ministry of Agriculture is actively promoting better methods. But it is equally obvious that much remains to be done to educate the public (1) in the need for cleaner milk, and (2) in the greater use of milk as a food.

Exhibition of Instruments, Drugs, Foods, and Appliances.

The usual exhibition was held in the Markets from July 21st to 25th. It was opened by Mr. W. G. Mumford, F.R.C.S., on behalf of the President-Elect, in the presence of a large gathering of representatives and visitors, on Tuesday morning. The Mayor of Bath (Mr. Cedric Chivers, J.P.) offered his congratulations to the Association on the great improvement in the Market Hall brought about by the floral and other decorative effects. Mr. Mumford said that one of the most important factors in the success of an annual meeting was the existence of such a commercial and educational exhibition as that before him. The advance of science had made it a far more complicated undertaking than in previous years, and this year some 80 stalls were furnished.

Cancer Research in Manchester.—For several years cancer research has been carried on in Manchester by the Christie Hospital, by the Pilkington and Helen Swindell's trust at the University, at the Radium Institute, and at the Royal Infirmary. The various research agencies are now coördinated by a committee which proposes to extend them. Dr. R. Veitch Clark (M.O.H., Manchester) is chairman of the general committee, Sir William Milligan is chairman of the executive, and Dr. E. M. Brockbank is chairman of the research committee. The work will have the strong support of the Ministry of Health, and a considerable programme has been arranged.

Correspondence.

"Audi alteram partem."

DISABLEMENT FROM CHRONIC RHEUMATISM.

To the Editor of THE LANCET.

SIR,—All those who are employed in physical treatment must have read with interest the letter on this subject in your issue of July 11th, for the nature of our work brings before us this particular class of sufferer in bulk. The amount of disablement and of suffering due to this cause is appalling, and the sooner something definite is done to reduce both the better. The object, however, of this letter is to emphasise four particular methods of alleviation.

(1) It is remarkable how many patients with non-articular rheumatism are found to be suffering from an habitual low fluid intake. Indeed, among women particularly, this error in diet would seem to have far more important bearing on the development of their rheumatism than any other single factor. Anyway, this much may be said, that while the daily fluid intake is reduced, and many of these patients habitually consume under a pint and a half a day, no form of physical treatment will help them. As soon as the intake is increased to four or more pints a day, other causes being absent, treatment becomes efficacious. This, of course, is simply a question of education, but one which is terribly neglected.

(2) The letter draws attention to the part played by endocrine disturbance in many of these cases and suggests, as did an annotation in THE LANCET of May 9th (p. 980), the possibility of endocrine therapy. This has, I think, been unquestionably established, although perhaps little realised. In a large percentage of the non-articular type of case, even when the fluid intake is adjusted, patients seem to develop a new focus of pain directly the old one has been cleared up. For some two years now it has been my custom, when this story becomes evident, to ask Dr. H. Gardiner-Hill to investigate the metabolism, and the frequency with which physical treatment becomes curative and not palliative as the result of scientific dosage with pituitary and thyroid has been most striking. Time after time complete failure has been turned into striking success. The same applies, only in lesser degree, to the articular varieties.

(3) Occasionally in similar cases metabolism is reported as correct, and, in the absence of obvious focal bases of infection, it is necessary to turn to less obvious foci. To the most important of these attention was drawn recently by Dr. A. E. Cumberbatch and Dr. H. Robinson at the Royal Society of Medicine in a communication which attracted far too little notice—namely, the value of diathermy in disinfecting the cervical canal. By this means again, time after time, apparently hopeless cases have proved to be completely curable, or, if not, the progress of disease has been arrested.

(4) It must not be forgotten that all cases of so-called rheumatism are not what they seem, and no form of physical (or medicinal) treatment which aims at the cure of rheumatism will cure either lumbago or the pseudo-sciaticas that are due to lesions of the sacro-iliac or lumbo-sacral joints.[1]

Of course, these four suggestions as regards possible treatment cannot in any way be supposed to touch more than the fringe of the trouble. There will still remain innumerable cases with which we shall have to grapple where infection arises from nose, teeth, tonsils, chest, and abdomen. The first and last often present apparently insuperable difficulties in their present state of our knowledge. But even so, a large amount of suffering and incapacity could be saved by the regular consideration even of these four points alone. I am, Sir, yours faithfully,

JAMES MENNELL.

Park-crescent, Portland-place, W., July 20th, 1925.

ANURIC DIABETIC COMA.

To the Editor of THE LANCET.

SIR,—In his valuable paper on the above in your issue of July 11th, Dr. A. O. Begg states that "clinically, the most prominent symptoms were vomiting, restlessness, and feeble, quick pulse." This is distinctly interesting; it brings the cases of anuric diabetic coma more or less into line with the toxæmia arising in acute intestinal obstruction. In this latter *condition the impaired renal function* has been imputed to an absorption of toxic proteoses formed in the distended gut; but I have shown that the absorption of such proteoses is unreasonable, and, moreover, that the evidence on which the opinion of the renal impairment was assigned (put forward by one set of workers at least) is untenable.[1] I put forward the plea that in acute intestinal obstruction the renal (and probably the hepatic) impairment is the direct result of the vomiting, straining, restlessness, and doubtless the abdominal distension. It occurs to me that the vomiting and restlessness in diabetic coma or in the pre-comatose state may be the effective cause, determining the anuria which Dr. Begg has occasionally noticed in his cases.

In spite of the fact that marked and persistent vomiting, however caused, makes people feel very ill, as, for instance, in prolonged sea-sickness—as *many of us from our own experience can testify*; in spite *of the pernicious effect of marked* and persistent vomiting in patients recovering from post-operative anæsthesia—patent to all surgeons; in spite of the fact that in pregnancy, persistent vomiting *causes* a toxæmia—an hepatic and renal derangement—as shown by the effect of stopping the vomiting—an end admitted of pre-eminent importance by all obstetricians; the idea that vomiting is a pathological force has not been received by the profession as reasonable. In this age of serums, vaccines, and toxæmias, in which so many diseases are imputed to endolytic poisons, physical causes are discounted. Yet what a toxæmia arises in uncompensated valvular cardiac disease; in pulmonary pathological processes (e.g., emphysema); in obstruction of the biliary and renal systems! Cut off or greatly diminish the blood flow through a part, how can it function normally, or the whole body be well?

It is true that Dr. Begg states that all patients with diabetes going into coma or already comatose, whether anuria arise or not, usually vomit; but I take it from his statement that the prominent symptoms of the anuric type are vomiting and restlessness, &c., that the vomiting and restlessness in those is greater than in the other, the non-anuric type. To understand how persistent vomiting can affect the kidney, we must realise that the blood in the renal artery has a choice of two paths: it can either go through the cortex or through the medulla (via the arteriæ rectæ); and that this choice is determined by the respective resistances in the cortex and medulla. When we remember that the urine is secreted in the cortex and flows through the medulla, so do we see that the pressure in the cortex (however small be the difference) must be greater than that in the medulla (as Brodie believed). With the compression of the kidney by the act of vomiting, all these channels for the moment are either obliterated or greatly narrowed, or tend to be; with the relief of the compression which follows the act, if the pressure of the urine in the medullary uriniferous tubules is less or much less than that of the blood in the arteriæ rectæ, so will the medullary capillaries be distended with a pressure effectually blocking the exit of urine from the cortical uriniferous tubules.

---

[1] THE LANCET, Sept. 22nd, 1917, and April 10th and 20th, 1921.

[1] The Toxæmia of Acute Intestinal Obstruction. H. K. Lewis and Co. 1923.

Clifford White has shown that in puerperal anuria (or oliguria) the renal tubules in the cortex are dilated; I have confirmed this in an experience of my own (not yet published). Dr. Begg states that in his cases of anuric diabetic coma the symptoms were those of obstructive suppression of urine. In these cases "certain changes" have been found "which suggest the kidney is an all-important factor." He promises us a further contribution on this part of the subject, which will be awaited with restless interest. Meanwhile, may I make two suggestions? The one is that Dr. Begg, in his cases of diabetic coma, should regard vomiting as an important pathological force, prone to determine renal aberrations. The other is clinical: that patients with this disease and impending complication should be placed on their side; that all means be adopted to limit or prevent vomiting; and that in the worst cases decapsulation of the kidney should be done. If the patient is to die, it makes no difference whether this event occurs in the theatre or ward; in eclampsia, patients almost in extremis have been saved by decapsulation; in diabetic coma, if the blood-sugar has been made to become normal by insulin, the objection to operation surely subsides. Decapsulation acts by relieving the cortical pressure (in which the capsule of the organ plays an important part); it allows blood to flow again through the cortical vessels, which distension of the uriniferous tubules prevented; and since blood can now flow through the cortex, there is less to go through the medulla; thus the block is removed, the vicious circle broken.

I am, Sir, yours faithfully,

Rugby, July 11th. R. H. PARAMORE, F.R.C.S. Eng.

To the Editor of THE LANCET.

SIR,—Dr. A. Clarke Begg classifies diabetic coma into two groups: one the usual type with acidosis and normal blood-urea; the other, the anuric type with slight or no acidosis, very high blood-urea, very high blood-sugar, and urine volume decreased even to anuria. This classification does not seem to me adequate. Last year Dr. E. F. Skinner and I reported in your columns[1] a case of diabetic coma with anuria, under the care of Prof. A. J. Hall, which cannot be placed in either of Dr. Begg's groups. The blood analysis in this case on admission yielded the following results (per 100 c.cm.): Blood-sugar, 0·957 g.; blood non-protein nitrogen, 110 mg.; plasma bicarbonate, 15·7 mg.; ketone bodies, 59·13 mg.; blood chlorides, 0·465 g. The low plasma bicarbonate and the degree of ketonæmia indicated a severe grade of acidosis not found in Dr. Begg's cases. Otherwise the findings are similar to those he observed in the cases of coma associated with anuria. It seems, therefore, necessary to consider at least two types of "anuric diabetic coma" according to the degree of concomitant acidosis.

I am, Sir, yours faithfully,

Sheffield, July 19th, 1925. C. GRAY IMRIE.

TUMORS AND CANCERS: A COMPLAINT.

To the Editor of THE LANCET.

SIR,—In your issue of May 23rd is a review of a work by Mr. Hastings Gilford on "Tumors and Cancers." This review struck me, as it has struck others, as an unjust and misleading statement of the nature and scope of the book. It conveys the impression that it is written by one who is himself a cancer researcher, in the narrowest sense of the word, and has taken advantage of the opportunity to make an onslaught on a book distinguished by its breadth and catholicity of view and which therefore puts his own particular work into its proper perspective. Some of his remarks were written obviously with the intention of creating prejudice. Thus one of the undoubted, if unavoidable, faults of the book is its bulk, but this bulk is largely due to the evident determination of the writer to support every statement with an ample backing of evidence. It is therefore an obvious and flagrant misstatement to say that the author's conceptions "are so often supported by simple assertions, by bad reasoning." Indeed a more logical or rational exposition of a difficult subject it would be hard to name. Such a statement could only have been made by one who had confined his reading to the "conclusions" and to mere glimpses at the main structure of the book. As for the other comments, some, such as that about alcohol, which is a truism, could have no other purpose than to bias the reader against the book. Then there is a grave and palpable omission. The reviewer is so occupied in his search for weak spots or for sentences which can by dislocation be made to appear gauche or ridiculous that he fails to do justice to the merits of the book. He dwells on those theoretical aspects and frills which he finds so disagreeable and says next to nothing of the real structure. In short, he displays his own personal feeling, but does not review the book.

Now, Sir, I should not have drawn attention to this subject now were it not for the circumstances that such a book as the book in question is so much needed at this juncture in order to form a background for recent achievements in laboratory research. It is therefore exceedingly unfortunate that an important volume containing such a recent and balanced outlook and review of cancer work in all its aspects should have been treated so scurvily by your reviewer.

Finally I may add that in writing as I now do I am expressing not only my own opinion but those of others who are equally impressed with the injustice that has been done and with the desire that the information contained in "Tumors and Cancers" should not be suppressed but should be broadcasted to all who wish to take a sane and just view of the present situation.—I am, Sir, yours faithfully,

Basingstoke, July 26th, 1925. NOLAN DALY.

THE REMUNERATION OF R.A.M.C. OFFICERS.

To the Editor of THE LANCET.

SIR,—The action of the British Medical Association with regard to the Royal Army Medical Corps recalls their similar action a few years ago with regard to the Royal Naval Medical Service. It is further an admitted fact that there is great difficulty in obtaining medical men for all three combatant services. It is to be hoped that the present dispute will lead to an exhaustive investigation of the lack of attraction to these great services. In my opinion a supply of good men will be obtained only if the opportunities to do first-class *medical and surgical* work and to keep themselves abreast with advances in their professional work are afforded. Such opportunities under existing circumstances are quite inadequate. Some time ago I submitted a comprehensive scheme to a committee, which included the Directors-General of the three medical services. It was damned with faint praise; but I do not despair that some such scheme may yet receive the official benediction.

I am, Sir, yours faithfully,
J. HERBERT PARSONS.

Queen Anne-street, Cavendish-square, W.,
July 23rd, 1925.

AN ACKNOWLEDGMENT.

To the Editor of THE LANCET.

SIR,—In connexion with the second edition of the "Encyclopædia Medica," Vol. XIII., article Diabetes, we have to regret that on p. 611 an acknowledgment was not made of the nomogram there represented to Dr. W. M. Feldman and Mr. A. J. V. Umanski, the authors of the article in THE LANCET, Feb. 11th, 1922, p. 273, where the nomogram originally appeared.

We are, Sir, yours faithfully,

Edinburgh, July 23rd. W. GREEN AND SON, LTD.

---

[1] THE LANCET, 1924, i., 14.

Obituary.

HARRY DRINKWATER, M.D., F.R.S. EDIN., M.Sc. (HON. CAUSA) WALES.

Dr. Harry Drinkwater, who died at his residence in Wrexham on July 11th at the age of 70, received his medical education at the Universities of Durham and Edinburgh, qualifying in the year 1877. Eight years later, at the M.D. Edin. examination, he took a gold medal for his graduation thesis. In 1890, after several years of practice at Sunderland, he removed to Wrexham, and was appointed physician to the Fever Hospital there. He became closely interested in the clinical diagnosis of diphtheria and other exudations in the throat, and in a carefully illustrated paper contributed to our columns in 1920 he showed how the distribution of patches of membrane may serve for provisional diagnosis of a very high degree of accuracy before bacteriological examination can be made; and, although some of his views were criticised, he gave good reason for his belief that diphtheria can be diagnosed without bacteriology. Dr. Drinkwater was a man of wide interests, a justice of the peace for the borough of Wrexham, a Vice-President of the Chester Natural History Society, and a member of the Linnean Society. Not long ago he presented to the Welsh Natural History Museum at Cardiff a collection of botanical studies from his own brush. Last year he published a little book setting forth the main lines on which medicine had progressed during his life time, a book calculated to revive the failing heart of pessimists who see only the fields untilled in medicine. A year ago he received the hon. M.Sc. from the University of Wales. Dr. Drinkwater was twice married and is survived by three children of the first marriage and by his second wife, whose is a medical graduate of London University.

WILLIAM MONTAGU VENABLES WILLIAMS, L.R.C.P. EDIN., D.P.H.

Dr. Venables Williams, who died on July 18th at Colwyn Bay in his sixty-eighth year, was one of the most respected and, until his health began to fail, one of the busiest practitioners in North Wales. He was the only surviving son of the late Rev. W. Venables Williams, formerly vicar of Llandrillo, and one of the founders of Colwyn Bay as a health resort. He studied at the Liverpool School of Medicine and at Edinburgh, qualifying L.R.C.P. & S. Edin. in 1882, and after middle life qualified for the post of medical officer of health by obtaining the D.P.H. He remained until his death health officer to the urban district of Colwyn Bay and honorary physician to the Colwyn Bay Cottage Hospital. He is survived by his widow.

THE LATE DR. HAROLD CLIFFORD.

WE briefly announced in our issue of July 18th the death of Dr. Harold Clifford at Manchester. Dr. Archibald Donald writes: "His death came as a shock to his friends. His health had not been good for some three or four years, but there had been nothing definite apart from a sudden loss of vision in April last due to intracranial hæmorrhage. But his eyesight had improved and he was in good spirits again. On July 5th he was ill with what appeared to be a gastric disturbance, and he died on July 7th from a severe cerebral hæmorrhage. You have already mentioned some of the many important posts which Dr. Clifford held in Manchester. He was a member of the North of England Obstetrical and Gynæcological Society for many years, and held the office of President in 1922. He was widely known as a wise adviser and a skilful surgeon in his own department and had a large practice.

"Dr. Clifford was handicapped for the struggle of life by ill-health. He gave an example of what could be accomplished by a courageous and resolute spirit in a frail body. He was never fitted for any form of severe physical exercise, and the recreation of outdoor games or any kind of sport was barred to him. As it was he found his pleasure in his work during the day, and in reading and in the society of his friends in the evening. He was an excellent host and seemed to be happiest when he was entertaining a small circle of friends. His manner was quiet, and although he held so many important appointments and had attained to a position of distinction in his special department, he preferred to remain in the background himself. He will be missed by a large circle of friends and perhaps most of all by his colleagues."

EVAN EVANS, M.B. CAMB., F.R.C.S. ENG., SURGEON LIEUTENANT-COLONEL.

THE death has occurred at Bury Port of Dr. Evan Evans in his seventy-second year. Studying at Cambridge and St. Mary's Hospital, he graduated as B.A. in 1882 and as M.B., Ch.B. in 1886. He became demonstrator in physiology and pathology at St. Mary's Hospital and clinical assistant in the ophthalmic department there and also at the Royal London Ophthalmic Hospital. In 1888 he took his D.P.H. and in 1894 became F.R.C.S. Eng. Dr. Evans settled in Llanelly, where for over 30 years he has been medical officer of health for Llanelly rural district. He was Surgeon Lieut.-Colonel of the 4th Batt. Welsh Regt. (T.F.) and an ex-President of the South Wales and Monmouth branch division of the B.M.A.

MARY EVA HASTINGS MORRIS, M.D. LOND.

AFTER a prolonged illness Dr. M. E. H. Morris died on July 11th at Bath, where she had been in practice for several years and where she had gained a large circle of friends. After studying at the London School of Medicine for Women she took the M.B. degree in 1902 and the M.D. in 1918. Before settling in Bath Dr. Morris was house surgeon in the North Devon Infirmary and physician to out-patients in the Bristol Royal Hospital for Sick Children and Women. In Bath she was school medical officer from 1908 to 1917, and she acted as assistant pathologist in the Bath War Hospital. There was a large congregation at the funeral service in Bath Abbey on July 15th, and on the following day the interment took place at Ystradmeurig, Cardiganshire.

RICHARD HENRY GRIFFITH, L.R.C.P. EDIN.

THE death took place at his home in Nevin, Carnarvonshire, of Dr. Richard H. Griffith on July 13th at the age of 61. He was taken ill on the Saturday previous when playing golf. Well known in athletic circles in North Wales, he was an ex-captain of Nevin and Abersoch Golf Clubs. An experienced yachtsman, he often acted as commodore at the annual regattas in South Carnarvonshire. After studying at University College, London, he qualified L.R.C.P. and L.R.C.S. Edin. in 1892, having been a house physician in the skin department in University College Hospital, London. Besides having a large practice, he was medical officer of health for the Pwllheli union. Dr. Griffith leaves a widow and one daughter.

WORK OF PENSIONS MINISTRY.—Major G. C. Tryon, Minister of Pensions, opening the new Ministry of Pensions Hospital in Mossley Hill, Liverpool, on July 14th, said that since the Ministry was started in 1917 it had spent in its efforts to alleviate suffering a sum which, including the present year, would have paid off the whole of the National Debt before the war. This year it was spending £86,000,000. At the height of this work in 1920 they were providing treatment, or arranging for it through the civil hospitals, for 160,000 men. Up to the present time, not counting allowances, £30,000,000 had been spent on actual treatment of the sick and wounded, and among the men who had passed through the hospitals were 39,000 who had lost limbs. The number now receiving treatment of various kinds was 40,000. The new hospital at Liverpool is part of a scheme for the reduction and centralisation of Ministry of Pensions medical institutions.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. E. R. Townsend is placed on the Retd. List with rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lieut. (D.) A. G. D. Pridham to be Surg. Lt.-Comdr. (D.).

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. G. Thomson retires on retd. pay on account of ill-health.

Maj. A. C. Vidal, half-pay list, late R.A.M.C., retires on retd. pay on account of ill-health.

Capt. J. Vallance retires, receiving a gratuity, and is granted the rank of Maj.

ARMY DENTAL CORPS.

Temp. Capt. E. H. C. Caute, from Gen. List, to be Capt.

TERRITORIAL ARMY.

Maj. A. Topping (late R.A.M.C.) to be Capt. and to relinquish the rank of Maj.

Capt. G. J. Linklater, from General Hospital List, to be Capt.

Capt. G. D. Yates, R.A.M.C., to be Divisional Adjt. 52nd (Lowland) Div., R.A.M.C., T.A., and School of Instruction, vice Capt. R. C. Aitchison, R.A.M.C.

Supernumerary for Service with the O.T.C.—University of Lond. Contgt., Sen. Div.: Capt. H. H. Woollard to be Maj. (Prov.).

The King has conferred the Territorial Decoration upon Lt.-Col. (Bt.-Col.) G. C. E. Simpson and Majs. A. A. Hingston and S. F. Linton.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. (Bt.-Col.) W. Bowater, from Active List, to be Lt.-Col. (Bt.-Col.).

Maj. E. J. Boome, from Active List, to be Maj.

ROYAL AIR FORCE.

Flight Lt. E. N. H. Gray is promoted to the rank of Squadron-Leader.

Flying Officer G. Clark is transferred to the Reserve, Class D.2.

DEATHS IN THE SERVICES.

Sir W. Launcelotte Gubbins, K.C.B., M.V.O., K.H.S., formerly Director-General A.M.S., who died recently, at the age of 75, from the effects of a cycling accident, was the son of the Rev. George Gubbins, Prebendary and Chancellor of Limerick. He graduated in arts and medicine at Trinity College, Dublin, in 1872, after passing a brilliant undergraduateship, being Erasmus Smith scholar. In 1873 he was gazetted as a surgeon in the army, and obtained his first experience in the field under the late Lord Roberts during the Afghan campaign of 1878. He was in medical charge of the 1st Battalion 5th Fusiliers in the operations in the Bazar Valley, and later became medical officer to Lt.-Gen. Sir Francis Maude, V.C., and saw much of the fighting in the Khyber Pass. Later he became divisional sanitary officer and secretary to the P.M.O. While still a junior in rank he was posted to Lord Wolseley's forces in Egypt during the suppression of the 1882 revolt, and after his promotion to Surgeon-Major in 1885 was sent out to India under Lord Roberts in the Burmese campaign. In 1894 he became Assistant Director at the War Office, his term of office embracing the period when the old Army Service became a Royal Corps, and he did much to develop the movement for voluntary aid in connexion with the Red Cross as a member of Lord Wantage's Committee. In 1899 he again served under Lord Roberts as P.M.O. to the 6th Division in the South African War with the local rank of Colonel, was at the relief of Kimberley, at Paardeberg, and entered Bloemfontein. Later he was in the Orange River Colony and the Transvaal, and was P.M.O. at Pretoria, Pietersburg, and on the northern line of communication. He received the commendation of Lord Kitchener as a capable administrator, who had accomplished much in the battle with enteric. On his return home he became P.M.O. on the Home District staff and was appointed to the Duke of Connaught's staff for the coronation of King Edward. The successful medical arrangements for the ceremony gained him the M.V.O., and soon afterwards he was promoted to Surgeon-General. Returning to India he became successively P.M.O. in Bombay and in the Eastern Command and chief of the Medical Division in India. In 1908 he returned to England, acted as Deputy Director-General, and two years later was made honorary surgeon to the King and succeeded Sir Alfred Keogh as Director-General of the Army Medical Service. During his term of office he greatly improved the physical standard of the army, and by the introduction of salvarsan much reduced the period of treatment in military hospitals of cases of syphilis. During the late war he was temporarily employed in various posts and keenly interested himself in the work of the British Red Cross Society, receiving for his services the reward for distinguished and meritorious service.

Medical News.

University of London.—The Committee of the Medical Members of the Senate have elected Sir Wilmot P. Herringham, K.C.M.G., C.B., M.D., F.R.C.P., to be their chairman for the year 1925–26.

Reader in Protozoology.—The title of Reader in Medical Protozoology in the University has been conferred on Mr. J. G. Thomson, M.A., M.B., Ch.B. Edin., in respect of the post held by him at the London School of Hygiene and Tropical Medicine. He was educated at the University of Edinburgh and has been lecturer in protozoology at the London School of Tropical Medicine since 1914.

In the recent examinations the following candidates satisfied the examiners:—

M.D. Examination.

Branch I., Medicine.—Percy C. Brett, St. Thomas's Hosp.; Gertrude B. G. Carden, London Sch. of Med. for Women; Edward Gallop, St. Bart.'s Hosp.; Paul C. Gibson, London Hosp.; Charles F. Harris, St. Bart.'s Hosp.; James L. Livingstone, King's Coll. Hosp.; William E. Lloyd (University Medal), St. Bart.'s Hosp. and Westminster Hosp.; Wilfrid P. H. Sheldon, King's Coll. Hosp.; John S. Sloper, St. Thomas's Hosp.; Richard H. Wade, St. Bart.'s Hosp.; and Samson Wright, Middlesex Hosp.

Branch III., Psychological Medicine.—Elizabeth C. Eaves, University of Sheffield and King's Coll. Hosp.

Branch IV., Midwifery and Diseases of Women.—Michael W. B. Bulman, London Hosp.; Macormack C. F. Easmon, St. Mary's Hosp.; and Winifred M. Gray, Hilda T. Haggett, Phœbe M. Phillips, and Elaine M. K. Salmond, London Sch. of Med. for Women.

Branch V., State Medicine.—Eleanor M. Reece, London Sch. of Med. for Women and Univ. Coll.

Branch VI., Tropical Medicine.—Khorshed S. Captain, London Sch. of Med. for Women and London Sch. of Tropical Med.; Henry C. V. Joy, London Hospital and London Sch. of Tropical Med.; Una F. M. Morton, London Sch. of Tropical Med. and Univ. Coll. Hosp.

M.S. Examination.

Branch I., Surgery.—Thomas G. D. Bonar, Guy's Hosp.; and John P. Hosford (University Medal), St. Bart.'s Hosp.

The following awards have been made in the Faculty of Medical Sciences at University College:—Cluff Memorial Prize (for proficiency in anatomy, physiology, pharmacology, and chemistry): R. M. Sargent. Anatomy: Gold Medal (Senior Class): Mary E. Sharp. Histology and Embryology: Prize equivalent to Silver Medal: Audrey Z. Baker and Margaret D. Wright (equal). Organic and Applied Chemistry: Silver Medal (General Course): D. F. Ogborn. Physiology: Gold Medal (Senior Class): J. R. Pierre. Pharmacology: Silver Medal (General Course): H. E. James.

University of Edinburgh.—At the graduation ceremony held on July 24th the following degrees were conferred:—

Doctor of Medicine.

Philip Barlow, *Ernest Bulmer, Sisir Chandra Chatterjee, †Leybourne S. P. Davidson (in absentia), Harold B. Dykes, Richard N. Gibson, David Landsborough, ‡Joseph C. Lorraine, ‡Kenneth A. T. Martin, ‡Solomon J. Rom, Sydney W. Smith, ‡Sahib Singh Sokhey (in absentia), May D. Stranger, ‡Brian G. Thompson (in absentia), †Thomas R. R. Todd, ‡Arthur R. Wightman, ‡Norman B. Williamson, and †Hedley D. Wright.

* Highly commended for thesis. † Awarded gold medal for thesis. ‡ Commended for thesis.

Master of Surgery.

Thomas B. Mouat.

Bachelor of Medicine and Bachelor of Surgery.

George L. Alexander, Christina W. Alston, Frank S. Anderson, George M. Anderson, Matthew D. S. Armour, Frank Ayrey, Ethel W. Barnley, John M. Bassett, David Bell, Hellet F. Bezuidenhout, James G. Bogie, Eleanor B. Bone, George I. Boyd, George G. Brander, Thomas Brewis, Anna M. Brown, James Brown, John S. Brown, William M. Brown, Joseph Bryant, Hsing Chang, James L. Chisholm, Ronald V. Christie, Robert Clark, *William J. A. Coldstream, Edwin G. Collins, John B. Colquhoun, John Comrie, Robert C. Craig, †Sidney

E. Croskery, John M. Davidson, Henry N. Davies, Eric F. Dott, Mary L. Drabble, George H. Duncan, Milad Luka El-Zik, Edgar L. Farrow, Jacobus C. Faure, Edward K. A. Firth, Charlotte E. Fisher, Charles G. Fletcher, Mary H. S. Forrest, Duncan H. Fraser, George Fraser, John A. Fullerton, Andrew N. Gardner, Margaret S. Gibb, Aubrey A. Gibbons, Alexander MacA. Gillespie, Silvio C. Walker, Alexandra A. Warnock, Alfred O. Watkins, John M. Watt, Dorothy Watterson, Barclay P. Webster, Lucien B. Wevill, John White, Janet Wilson, and Ai Sung Wong.

* First-class honours. † Second-class honours.

The following awards have been made: Cameron Prize in Practical Therapeutics: Dr. R. Magnus, Professor of Pharmacology, University of Utrecht. Goodsir Memorial Fellowship: Adam D. Macdonald. Gunning Victoria Jubilee Prize in Physiology: William G. Millar. Gunning Victoria Jubilee Prize in Surgery: Harold K. Corkill. Chiene Medal and Prize in Surgery: Thomas B. Mouat. Ettles Scholarship and Leslie Gold Medal: William J. A. Coldstream. Allan Fellowship in Clinical Medicine and Clinical Surgery: John G. Kininmonth. Murchison Memorial Scholarship in Clinical Medicine: Sidney E. Croskery. M'Cosh Graduates and Medical Bursaries: Hilta Inès Christina Pfister. Mouat Scholarship in the Practice of Physic: William J. A. Coldstream. Buchanan Scholarship in Gynæcology: Robert W. Smith. James Scott Scholarship in Midwifery: John G. M'Crie. Lauder Brunton Prize in Pharmacology and Therapeutics: Andrew R. Gilchrist. Beaney Prize in Anatomy and Surgery: John G. Kininmonth. Conan Doyle Prize: Hyman Felix Schiller. Annandale Gold Medal in Clinical Surgery: William J. A. Coldstream. Scottish Association for Medical Education of Women Prize: Hilta Inès Christina Pfister. Dorothy Gilfillan Memorial Prize: Hilta Inès Christina Pfister. Sir Robert Jones Prize in Orthopædic Surgery: Alexander W. Sanderson. Pattison Prize in Clinical Surgery: John Thomson. Wellcome Medals and Prizes in the History of Medicine: Gold Medal, Alexander Haddow; Silver Medal, Bryan Williams. Cunningham Memorial Medal and Prize in Anatomy: George I. H. Braine. Whiteside Bruce Bursary: Thomas P. Bliss.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on July 21st, Sir Harold J. Stiles, President, in the chair, the 28 successful candidates out of 58 entered, who passed the requisite examinations between March 30th and April 6th, were admitted Fellows:—

George J. Alexander, Leslie C. L. Averill, George H. Buckley, John A. G. Burton, Ernest Y. Comrie, Leopold R. de Castro, William A. Ekanayake, Doris C. Gordon, William P. P. Gordon, Reginald D. McK. Hall, Robert B. Hare, Charles F. W. Illingworth, Noel Kemm, Noel Kretzmar, Ramkrishin Harbhagwandas Lala, Claude H. Marshall, Finlay S. Mayne, Donald S. Middleton, Oswald O. Popper, Frank N. Reynolds, Edward H. Richards, Donald E. Ross, Cyril R. Sandiford, Robert Selby, John McD. S. Slater, Jacob W. van Reenen, Stewart A. Wallace, and William H. O. Woods.

The following candidates, having passed the Final Professional Dental Examination, have been granted the diploma of L.D.S. R.C.S. Edin.:—

Guthrie Russell, Douglas Sutherland, John Balfour, Albert G. Ueckermann, Ernee K. Wilson, Lewis W. G. Watson, Alastair O. Couston, John J. Seaton, William Mason, Margaret I. MacTaggart, and Mela Itam Soni.

SCHOOL FOR PRE-TUBERCULOUS CHILDREN.—At the annual meeting of the Liverpool Hospital for Consumption on July 22nd it was decided to provide and maintain an open-air school and hospital for pre-tuberculous children. This will be the first of its kind in the north of England.

HARROGATE ROYAL BATH HOSPITAL.—On Monday, August 10th, Princess Mary, Viscountess Lascelles, will open the new bacteriological and biochemical department at this hospital. The Earl of Harewood, G.C.V.O., will preside.

FINANCE OF THE GENERAL NURSING COUNCIL.—The income of the General Nursing Council for the year ending March 31st last was £27,505, and the expenditure £20,042. Examination fees produced the large sum of £12,301; the fees paid to examiners amounted to £4580. The Council has £20,000 invested and a further £5000 in the bank.

REGISTERED NURSES.—The new Register of Nurses contains 42,173 names, but recent additions have brought up the number to over 47,000. Some thousands of applications for registration received during the closing days of the period of grace have yet to be dealt with, and when they have been disposed of the total number of State-registered nurses will probably exceed 50,000. In future registration will be by examination.

CANCER RESEARCH IN YORKSHIRE.—It has been decided by the Yorkshire Council of the British Empire Cancer Campaign to appeal to the county for £75,000 for research work. Most of this work will have to be conducted at the Medical School of Leeds University, but Sir Berkeley Moynihan points out that the school has "no proper habitation" and that its equipment is inadequate.

MEDAL AWARDED TO BLOOD DONOR.—The Minister of Health on July 27th presented the Meritorious Service Medal of the Order of the British Empire to Mr. Bertie Wallace Tibble in recognition of his public-spirited work as a blood donor to the London Hospital. Mr. Tibble has given a pint of blood on more than 50 occasions, and although of small means has always refused the usual payment of 5 guineas for his service.

DUBLIN HOSPITALS.—In a speech at the Dublin Rotary Club, Sir W. de Courcy Wheeler declared that there are far too many hospitals in that city and that some of them are totally out of date. They lack lifts and patients have to be carried from the operating theatre along corridors and up staircases. Sir William Wheeler suggested that four or five of the hospitals might well be amalgamated, and laid especial stress upon the desirability of children being dealt with outside the city.

BAN ON UNVACCINATED SEAMEN BY U.S.A.—On July 14th a test case of importance to shipowners and seamen was heard at Liverpool City police-court, when a ship's fireman claimed for arrears of wages. It appears that when the ship arrived at Vancouver the crew were informed of a new American regulation that no ship could be allowed to enter the port unless the master could produce a certificate from the American consul in the last port of call saying that all the crew had been vaccinated during the last 12 months. Three firemen, including the plaintiff, stated that they had never been vaccinated and had conscientious objections to vaccination. They were left behind in Vancouver and the ship returned after a voyage to the United States and picked up the three again at Vancouver. After arguments by counsel, the magistrates decided that the men were merely put ashore, that the men had not signed off, and found for the sum claimed. The importance of the case lies in this new drastic protective regulation by the United States Government.

FIRST INTERNATIONAL MALARIA CONGRESS.—This Congress will be held at Rome under the patronage of the Italian Government on Oct. 4th, 5th, and 6th. Amongst others, the following subjects will be discussed: (1) Anopheles and malaria, (2) biology of the parasites (unicity and plurality of the parasites), (3) the alkaloids of quinine and the therapy of malaria, (4) epidemiological factors and antimalarial measures, (5) propaganda (statistics), (6) inoculation fever. All medical men will be admitted to the Congress, and the official languages will be English, French, German, Italian, and Spanish. All communications to the Congress should be sent to the secretary not later than Sept. 20th, and manuscripts or communications for distribution should arrive before Sept. 1st. Hotel accommodation will be provided by the Executive Committee of the Touring Agency, Ente Nazionale Industrie Turistiche, of Piazza Colonna, Rome, who will also supply any information useful to travellers. Applications for accommodation should be received by the secretaries of the Congress at 14, Via XXIV. Maggio, before Sept. 20th. A fee of Lir.100 will be charged for each member of the Congress.

UNIVERSITY OF PARIS.—A vacation revision course will be held at the Hôtel-Dieu from Sept. 14th to 25th. The subject will be Recent Medical and Surgical Views on Diseases of the Digestive Tract, fully illustrated by demonstrations of all kinds. Following the course there will be a study tour to Vichy. Further particulars may be obtained from the Clinique Médicale de l'Hôtel-Dieu, Paris.

BIRTH CONTROL CLINIC.—The original clinic for constructive birth control, founded by Dr. Marie Stopes and Mr. H. V. Roe at Holloway, has removed to more central quarters at 108, Whitfield-street, Tottenham Court-road, W. 1. Nurse N. Jones, who gained the C.B.C. certificate after training at this clinic has been put in charge of the birth control clinic recently opened by the Abertillery and District Hospital.

GUY'S HOSPITAL: A YEAR'S WORK.—The report of Guy's Hospital for 1924, which has just been issued, shows that during the year 9495 patients passed through its 616 beds, as compared with 8765 in 1921, yet the average number of days' residence (21·25) remained practically constant. It is claimed that this is "the result of careful organisation in reducing to a minimum the number of vacant beds." Adding the number of patients in the hospital at the beginning of the year, the total number who received treatment in the wards was 10,017, the largest ever recorded in 12 months. The out-patients numbered 124,000, and in this department a whole-time clinic for the treatment of venereal diseases has been opened. Between 1923 and 1924 the number of attendances for massage increased from 26,791 to 31,106; for remedial exercises the growth was even more remarkable—namely, from 4443 to 14,013. With a total expenditure of £158,000, the deficiency on income and expenditure account was less than £2000, thanks to a large increase in legacies. At the end of the year there were 267 nurses in training.

DONATIONS AND BEQUESTS.—By the will of the late Sir Rickman Godlee, the testator left, on his wife's decease, among other bequests, £5000 to the Royal Medical Benevolent Fund; £5000 (to include the amount of his debentures in that Society) to the Royal Society of Medicine, to be applied as far as possible for the purposes of the library of the Society; £10,000 upon trust for investment, and to apply the income in travelling scholarships for students of University College Hospital Medical School who had held a house surgeoncy and one other resident appointment at University College Hospital, and are, in the opinion of the committee, likely to benefit from visiting medical schools and scientific institutions abroad or in this country. If, in the opinion of the committee, there should be a more suitable form of post-graduate study the scholarships may be applied for this purpose, in the discretion of the committee. He stipulated that in the event of the hospital being taken over or maintained by the State or municipality or other public authority this trust should continue as a permanent fund to benefit students in the way indicated and not be merged in some general "educational trust." He also left £1000 to the Whitchurch District Nursing Association, offered as an endowment.—The late Mr. William Henry Armitage, of Buxton, left £1500 to the Manchester Children's Hospital, Pendlebury, for a cot; £1500 to the Salford Royal Hospital for a cot; £1000 each to the Manchester Royal Infirmary, Ancoats Hospital, St. Mary's Hospital, Manchester, and the Manchester and Salford Blind Aid Society; £500 each to the Manchester Ear Hospital, the Manchester Royal Eye Hospital, and the Manchester and Salford Hospital for Skin Diseases; £300 each to the Manchester and Salford Sick Poor and Private Nursing Institution, the Manchester City League of Help, and the Salford Civic League of Help; £200 to the Society for the Prevention of Cruelty to Children; £200 to the Boys' and Girls' Refuges, Strangeways; £100 to the Salford Lads' Club; and £100 to the Cinderella Club, Withy Grove.—As a result of the wireless concert organised by the Daily Graphic and Allied Newspapers, Ltd., £3853 will go to funds of the Infants Hospital, Westminster.—Alderman E. Dickinson, J.P., Wigan, left £250 to the Royal Albert Edward Infirmary, Wigan, to be invested for the annual provision of Christmas gifts for the children's in-patient department, and £1000 for the endowment of a bed.—During the year for the Hospital Sunday and Saturday Fund, Carlisle, £3200 was collected and distributed as follows: Cumberland Infirmary £2333, Carlisle Dispensary £242, Silloth Institute £185, Carlisle Fever Hospital £50, Carlisle Nursing Association £60.—Legacies of £1347 from the executors of the late Mr. Joseph Bell and £450 from the late Mr. Joseph Milnthorpe have been received by the Manchester Royal Infirmary.

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, JULY 23RD.

The Public Health Bill.

THE House went into Committee on the Public He
Bill (a measure which consolidates a number of provis
contained in private Acts and makes them applicabl
the country generally). The EARL of DONOUGHMORE wa
the chair.

Lord BANBURY of SOUTHAM moved to leave out Clause
which provides for the removal to hospital of infect
persons suffering from pulmonary tuberculosis at
instance of the county council or the local authorit
cases where the lodging or accommodation occupied by
patient is such that proper precautions to prevent
spread of infection cannot be taken or are not being ta
He said that the clause seemed to be likely to give ri
very considerable expense, to interfere with the exis
hospitals, and to be of the nature of "grandmothe
legislation. Apparently everybody who was in ill-he
was now to be provided for by the State or by the
payers.

Lord EMMOTT (who was in charge of the Bill) said
he thought the clause was a very valuable one. It was
for the purpose of spending money, but for the purpo
taking steps where necessary to protect the public
infection. Pulmonary consumption was a highly infec
disease, and if the local authorities had not power to
with it, it was possible for it to spread very consider
There were great safeguards in the clause. First, its a
cation was limited to patients whose surround
prevented the adoption of proper precautions, and in
event it must be shown that serious risk of infection a
In the second place there was a requirement that the re
ing institution should have consented to the receptio
the patient, and that suitable accommodation existed.
the third place there was a requirement that the co
removal to, and maintenance in, the hospital shoul
borne by the county council or local authority. At
rate, that removed injustice from the individual. In
fourth place the period of detention was limited, and i
fifth case an application could be made on behalf of
patient to the court for the rescission of the order at
time after six-weeks from the date of the order.

The amendment was negatived.

On Clause 63, which deals with the extended u
ambulances, and allows people leaving hospital, not h
suffered from any infectious disease, to be put into veh
which have previously carried cases of infectious dis
provided that suitable precautions are taken to pr
the communication to any person of infectious disease

Lord DYNEVOR moved an amendment providing tha
each occasion a certificate should be signed by a regis
medical practitioner, so that it might be quite certain
proper precautions were taken against the spread of dis

Lord EMMOTT, in resisting the amendment, said th
would cause great delay and considerable expense an
did not think that it would add at all to the safety o
public and of the patients.

Lord DYNEVOR said that if the noble lord was
certain that no infection would be spread he would
press the amendment.

The amendment was withdrawn.

On Clause 64, which gives a local authority pow
make reasonable subscriptions or donations to a volun
hospital or institution, if it is satisfied that by so doi
will maintain, or extend, or increase the efficiency of ho
accommodation for the sick inhabitants of the district

Lord BANBURY moved to delete the clause on the gr
that it opened up a great vista of expense to the
payers. It would militate, he said, against the p
subscribing to the voluntary hospitals. It was an att
to provide State hospitals, which he thought was wro

Lord EMMOTT said he thought that it was possible
the clause would be a saving rather than a spending
There were many cases in which hospitals found it e
ordinarily difficult to live, and just a little bit of
from the local authority might enable them to keep g
It would not cause the hospitals to become public in
tions more than they were to-day.

The EARL of MALMESBURY thought that it was the
end of the wedge against the voluntary system if
introduced grants from public authorities.

The Lord Chancellor (Viscount Cave) said that no one would be more unwilling than he that the hospitals should cease to be voluntary, and come upon the rates. But for all that he was strongly in favour of this clause. He did not think that it would in the least endanger the voluntary character of those institutions. The local authorities who employed large numbers of workmen owed a great debt to local hospitals.

Lord Stuart of Wortley said he knew a town in which a contribution of a penny in the pound on wages by employers, as well as by the employees, had produced a sum which had placed the hospitals out of the reach of serious financial necessity. Could anyone say that in that case the local authority as a large employer of labour should not contribute its small quota to that desirable result? It was possible that the clause might be amended so as to limit it to contributions in respect of a municipality's own employees.

Lord Emmott said that there had always been some doubt in carrying out Section 131 of the Public Health Act, 1875, as to whether it did not contemplate that special accommodation should be provided at the hospital for the subscription paid, and whether subscriptions by the local authority in response to appeals from the hospital were authorised. It was to remove that doubt that the clause had been inserted in the Bill. There were already many such provisions in local Acts.

Lord Banbury said he had no objection to the amendment proposed by Lord Stuart of Wortley. If the noble lord would draft an amendment on the lines suggested and consult him afterwards he would withdraw his own amendment now with a view to another amendment being moved on the report stage.

The amendment was withdrawn.

The Committee stage of the Bill was concluded and the Bill was reported to the House.

Summer-Time Bill.

On the motion of Lord Desborough the Summer-Time Bill, which has already passed through the House of Commons, was read a second time.

Tuesday, July 28th.

Dangerous Drugs Bill.

Viscount Cecil of Chelwood (Chancellor of the Duchy of Lancaster), in moving the second reading of the Dangerous Drugs Bill, which amends the Dangerous Drugs Acts of 1920 and 1923, so far as is necessary to enable effect to be given to the Opium Convention, signed at Geneva on Feb. 19th last, said that the measure was not a contentious one, and was necessary because the Convention could not be ratified without some slight changes in our law. It was very important that the Bill should be passed before Parliament adjourned in August, because the Government were very anxious to ratify the Convention at the earliest possible moment. The first clause of the Bill extended the Dangerous Drugs Acts of 1920 to coca leaves and Indian hemp. The second clause made a small change in the machinery of The Hague Convention, under which these things had hitherto been governed. The third clause brought up to date, in accordance with scientific opinion, the definition of certain alkaloids, such as morphine, heroin, ecgonine, and things of that kind, which had been more carefully defined by the assistance of the experts at Geneva. Clause 5 gave power to strike out from the list of dangerous drugs those drugs which, by experience, had been found not to be capable of being used by addicts, and were therefore no longer to be classed as dangerous.

The Convention represented a very valuable advance in the struggle to bring under control the use of these drugs, and primarily the drugs and substances referred to in the Convention. There were three broad divisions of the subject dealt with by the Convention. There was raw opium, which was used for eating in India, which really was not an international question at all. It was concerned only with what the Indian Government allowed its Indian subjects to do with the opium grown in India. Then there was opium smoking which, apart from a few relatively unimportant exceptions, was a purely Chinese question. Practically it was only the Chinese who indulged to any extent in opium smoking. The large growth of opium in China and the unhappy condition of that country at the present time rendered it impossible to control in any way the illegitimate export of the drug.

By far the most important subject dealt with by this Convention was the question of the use of these very formidable drugs—heroin, morphine, cocaine, and the like. It was a very serious evil even for this country, and still more serious for other countries, in some of which those who trafficked in these drugs had even pushed their pernicious wares in the schools, thus leading children into vice. The evil was rendered all the more formidable by the fact that behind the traffic there were apparently syndicates with very considerable financial resources. He was glad to be able to assure their lordships that owing to the efforts of the Home Office the evil was not a growing one in this country, but was to a very large extent under control here. There was no doubt that international control of the traffic in these drugs would make it very much less easy for people dealing in them to find means of pushing their pernicious wares. The main purpose of the greater part of the provisions of these conventions was to institute international supervision and control of the traffic in these drugs. It was not so hopeless or so difficult a matter as one might assume at first sight, because the drugs were only manufactured in a very small number of factories—he thought there were not more than ten—and if proper national control could be obtained over these factories and international control over the traffic from them they might hope to assist in diminishing the trade. He would like to pay a tribute to the great services of the gentleman who preceded him as the representative of this country in these conferences and who had done more, perhaps, than any living man to carry forward the struggle against the illegitimate use of drugs. He referred to that exceedingly able member of the staff of the Home Office, Sir Malcolm Delevigne.

Viscount Haldane supported the Bill.

The Bill was read a second time.

Therapeutic Substances Bill.

The Commons' amendments to the Therapeutic Substances Bill were considered, and on the motion of Viscount Gage all the amendments were agreed to, except in respect of a slight modification to that which provided that a regulation should be modified or annulled following the voting of an address by either House of Parliament.

HOUSE OF COMMONS.

Wednesday, July 22nd.

Death-rates among Commercial Clerks.

Lord Henry Cavendish-Bentinck asked the Minister of Health whether, in view of the heavy death- and tuberculosis-rate among commercial clerks, owing to the insanitary, overcrowded, and badly lighted condition of the offices in which they worked, he would introduce legislation to give local authorities further powers to secure the better regulation of such offices.—Sir Kingsley Wood replied: Other circumstances besides the condition of offices go to account for the present death- and tuberculosis-rates among commercial clerks. Local authorities already have certain powers to deal with conditions in offices, and my right hon. friend cannot at the present time promise further legislation.

Protection of Civilians against Poison Gas.

Mr. Cecil Wilson asked the Secretary of State for War whether he was aware that in many countries scientific investigation was taking place regarding the most deadly forms of poison gas and other inventions designed to exterminate human life; whether any steps were now being taken in this country, or when would they be taken, in instructing the civil population as to any means whereby they might protect themselves; and whether he could indicate to the House what such steps were.—Sir L. Worthington-Evans replied: The answer to the first part of the question is in the affirmative. As regards the remainder of the question, the measures to be taken for the protection of the civil population against poison gas are now being considered by the Committee on Imperial Defence.

Thursday, July 23rd.

School Medical Services.

The House went into Committee of Supply on a vote of £35,852,751 for the salaries and expenses of the Board of Education, Mr. J. Hope in the chair.

Mr. Fisher said when he was President of the Board of Education nothing was more encouraging than the reports received from his inspectors as to the health and general well-being of the children in the elementary schools. He would like to know whether the reports which the Board now received were equally satisfactory in this respect. Although it was true that, very largely owing to the skill, energy, and devotion of the school medical services, the health of our school population had been greatly improved, nevertheless it was true that there were still great defects to be remedied. He noticed, for instance, that in the last report of the Board of Education it was stated that there were 200,000 children mentally or physically defective who had not yet received places in special schools. Owing to the great expense of such schools he quite believed that it would be sanguine to expect this deficiency to be made up immediately, but he noted with pleasure that the President of the Board was pressing the local education authorities to do their best to make up the deficiency, and he trusted that he might receive some support from the private benefactor.

Dr. HADEN GUEST said it seemed to him that they ought, in view of the very satisfactory nature of the results which had flowed from medical inspection, to increase the amount of health work and health care of children and not diminish it. That should apply to all the schools in the country, irrespective of whether they were public schools or others. He believed that the extension of medical health work to all schools would have exceedingly valuable results. He also wished to refer to the fact that some 10 per cent. of the children attending elementary schools were never adequately fed. He should like to see the Board of Education insist on the standard of physical well-being and feeding of children being raised very considerably higher than it was at the present time. It should be the business of the medical officer and the school inspector to draw up a list of children who would benefit by increased nourishment, and it ought to be part of the school curriculum to provide school meals which could be either paid for or given free to the children who required them. That was a method of practical Communism which would commend itself to both sides of the House.

The DUCHESS of ATHOLL (Parliamentary Secretary to the Board of Education), replying to Mr. FISHER, said the last report of the chief medical officer of the Board gave some very comforting figures. In 1923 30·7 per cent. of the children in the schools inspected had defects of one kind or another compared with 44 per cent. in 1894. That was certainly progress. In the same year there were 5·9 per cent. who had been diagnosed as under-nourished as compared with 12·8 per cent. in 1913. It was found that children suffering from defective hearing were only half what they were ten years ago. The work was carried on unobtrusively and was not spectacular, but day in and day out it was going on steadily.

The vote was agreed to.

Lead Poisoning and the Pottery Industry.

Mr. CLOWES asked the Home Secretary the number of fatal cases of lead poisoning in the pottery industry last year; what were the ages of the persons who died and the nature of the process worked; and what was the length of time each of the deceased had been employed on lead processes.—Sir W. JOYNSON-HICKS replied: The following are particulars of deaths from lead poisoning in the pottery industry for the year 1924:—

Case No.	Sex.	Age.	Occupation.	Duration of employment in lead processes.
1	M.	46	Glost placer.	16 years.
2	M.	65	"	Believed many years.*
3	M.	51	"	29 years.
4	M.	51	"	36 "
5	M.	55	Dipper.	38 "
6	M.	50	Oddman.	Many years.
7	M.	59	Glost placer.	47 years.
8	M.	63	"	At least 18 years.
9	M.	44	"	Many years.
10	M.	54	"	33 years.
11	M.	53	Dipper.	25–30 years.
12	M.	46	"	20 years.
13	M.	51	"	42 "
14	M.	54	Glost placer.	36 "
15	M.	48	Dipper.	32 "
16	F.	50	Ware cleaner.	20 "
17	F.	57	"	30 "
18	F.	35	Majolica paintress.	14 "

* But has not worked since 1912 on account of lead poisoning.

Committee on Child Assault.

Lady ASTOR asked the Home Secretary whether the Committee on Child Assault had finished taking evidence; and when it was anticipated that their report would be issued.—Sir W. JOYNSON-HICKS replied: The Committee are now considering their report, and I hope it may be issued soon after the summer holidays.

Insurance Contributions in Rural Areas.

Lieut.-Colonel HENEAGE asked the Minister of Health whether, seeing that the benefits authorised under the Health Insurance Act were greater in those societies composed mostly of rural workers as compared with those in purely urban districts, and that the former societies had created greater surpluses per person insured, he would consider authorising a reduced contribution under the National Health Insurance Act from those living in rural areas.—Mr. NEVILLE CHAMBERLAIN replied: Pending the report of the Royal Commission now in session I could not properly make such a change in the National Health Insurance system as is suggested. I may add that approved societies can repay as an additional benefit out of accrued surplus the whole or part of the contributions of their members, and accordingly societies composed mainly of rural workers and having a favourable sickness experience can now provide the normal benefits at an annual cost to members less than the product of the normal contribution.

Houses Unfit for Habitation.

Mr. TREVELYAN THOMSON asked the Minister of Health the number of houses which he estimated were not reasonably fit for human habitation in both urban and rural areas.—Mr. NEVILLE CHAMBERLAIN replied: Statistics on the point raised by the hon. Member are not available. According to the latest annual reports of medical officers of health there were 291,700 houses in urban districts and 30,954 in rural districts found on inspection not to be in all respects reasonably fit for one reason or another. During the same year defects were remedied in 12,987 houses in urban districts and 49,530 in rural districts.

Disease-carrying Mosquitoes.

Mr. FOOT MITCHELL asked the Minister of Health whether the available statistics showed any diffusion of disease-carrying by mosquitoes in this country; and whether any advice had been given to local authorities as to the desirability of eliminating likely breeding-places.—Mr. NEVILLE CHAMBERLAIN replied: I am advised that, apart from occasional casualties arising from the inflammation of mosquito bites, mosquitoes in this country are not known to carry disease other than malaria. The known cases of indigenous malaria arising in this way are very few, only four such cases have been reported during 1924.

Preservatives in Food.

Mr. SUTTON asked the Minister of Health whether independent scientific investigations had been made by his department as to the physiological effect of the use of preservatives in food; whether any and what offers had been made by manufacturers or others to combine with the department in pursuing such investigations; and whether he would arrange for inquiry to be pursued by means of independent investigation before proposing final regulations dealing with the subject.—Mr. NEVILLE CHAMBERLAIN replied: The physiological effect of the use of preservatives in food was one of the matters considered by the recent Departmental Committee on Preservatives and Colouring Matters in Food, which included a number of distinguished physiologists in no way connected with the Government or the trades concerned. I have had an offer from one large firm interested in the production of boron compounds to coöperate in a further inquiry into the effect of the consumption of small quantities of such compounds in food, but having regard to the full consideration which was given to this matter by the Committee I do not think it necessary to institute any further inquiry.

Value of Tuberculin Tests.

Mr. HURD asked the Minister of Agriculture if he was aware of the uncertainty that existed as to the value of the different tuberculin tests and the consequent discouragement of the increased production of graded milk; and whether he would issue a circular indicating what, in the opinion of the Ministry, was the best method of clearing a herd of tuberculosis and generally advising farmers in this matter.—Mr. WOOD replied: The Ministry has under consideration the investigation recently conducted under the auspices of the Medical Research Committee on the trustworthiness of various tests with tuberculin. My hon. friend will also realise that very varying conditions prevail among the herds of this country, and I am therefore doubtful whether at the present time a circular of the kind suggested would fulfil the purpose he has in view. The Ministry is always prepared to advise in cases of special difficulty.

FRIDAY, JULY 24TH.

Therapeutic Substances Bill.

The House went into Committee on the Therapeutic Substances Bill, Mr. J. F. HOPE in the chair.

On Clause 3, which deals with the restrictions on the importation of therapeutic substances,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) moved an amendment making it lawful to import any serum of foreign origin for which no standard existed, provided that the substance complied with the general regulations governing the quality and general purity of substances of the same class. He explained that as originally drafted the clause might have prohibited the importation of such a substance as the Spahlinger serum.

Dr. SHIELS moved an amendment to the amendment designed to allow a substance such as the Spahlinger serum to be consigned for test purposes to any medical practitioner in the country.

Sir K. WOOD said that the Government could not assent to the importation of sera without examination.

The amendment to the amendment was withdrawn and Sir K. Wood's amendment was agreed to.

On Clause 4 (*which deals with joint advisory committees*) an amendment was agreed to adding a member to be appointed by the British Medical Association to the advisory committee which is to assist the joint committee in framing *regulations* under the Bill.

On Clause 5 (which deals with the power to make regulations) Sir K. WOOD accepted an amendment moved by Captain W. BENN giving Parliament the power to move *an address praying for the modification or annulment of* regulations which had been laid before Parliament.

The amendment was agreed to.

The Committee stage was concluded and the Bill as amended was reported to the House.

Diseases of Animals Bill.

The House went into Committee on the Diseases of Animals Bill.

Mr. A. V. ALEXANDER moved an amendment to Clause 1 (which provides for the repayment by the Minister to local authorities of three-quarters of the amount of compensation paid by them for cattle slaughtered on account of the existence or suspected existence of tuberculosis). The amendment proposed to make this repayment dependent on the Minister being satisfied that no carcass, or portion of a carcass, had been, or would be, used for human consumption.

Mr. E. WOOD (Minister of Agriculture) said that the total condemnation of a carcass on evidence of local tuberculosis was unnecessary and wasteful. While he could not accept the amendment he would amend the Tuberculosis Order to provide that a veterinary inspector should send notice in writing to the medical officer of his intention to slaughter an animal under the Order, and that he should not remove a carcass or offal until he had received a notification from the medical officer stating whether any part of it might be disposed of for human consumption.

Dr. SHIELS thought there should be no room for suspicion in this matter, and the procedure should be along the line of "safety first."

Sir R. LUCE said that tuberculosis was localised in a large proportion of cases and there was a very large consensus of opinion in the medical profession that there was practically no danger in the use of a large portion of the carcasses of animals affected only by a local form of the disease. The amendment would lead to wasteful action.

Dr. DAVIES said that the consensus of medical opinion was definitely against the mover of the amendment. The danger anticipated from anything circulating in the blood of these animals was very much exaggerated, and it might *be absolutely ignored.* There was no danger of tuberculosis being carried by the blood-stream except in the case of a cow with acute general tuberculosis, and such animals were always destroyed.

Mr. ALEXANDER said he would withdraw the amendment on the understanding that if he was dissatisfied with the actual terms of the proposed alteration in the Tuberculosis Order he could raise the point again on the third reading of the Bill.

The amendment was withdrawn. The Committee stage was concluded and the Bill was reported to the House.

MONDAY, JULY 27TH.

Spahlinger Treatment.

Mr. MACANDREW asked the Minister of Health if he was aware that the sanatorium committee for Ayrshire was unanimously of opinion that the Government should contribute towards experiments with Mr. Spahlinger's treatment of tuberculosis; and what steps he proposed to take to assist in the encouragement of experiments with this treatment.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the negative. As regards the second part, I would refer my hon. friend to the answer which I gave on the 9th inst. to the hon. Member for Bedwelty on the subject of the Spahlinger treatment.

Withholding of Addresses of Mental Patients.

Sir DAVISON DALZIEL asked the Home Secretary whether his attention had been called to the dissimilarity of decisions regarding the alleged criminality of withholding addresses of patients escaped from mental institutions; whether he would investigate the circumstances under which a Mrs. Gibbons, of Trinity-square, Brixton, was sentenced at the Lambeth police-court to two months' imprisonment for this offence and hurriedly released from Holloway ten days later; and whether he could give the decisions in police-court proceedings of this nature in 1923, 1924, and the first six months of 1925.—Sir W. JOYNSON-HICKS replied: In Mrs. Gibbons's case I felt justified by the facts that came to my knowledge in recommending a remission of the balance of the sentence. No other case of the kind has been brought to my notice, and the Home Office have no information of other cases of the kind that may have been dealt with by courts of summary jurisdiction.

Scientific Research.

Captain MACMILLAN asked the Secretary to the Treasury whether, in arriving at the total of £1,045,000 provided in the estimates, 1925–26, for scientific research, distinction was made between research, development, and experiment; whether he would give a detailed statement showing the different items of the total mentioned; and the sum spent on scientific research carried on purely for the advancement of natural knowledge and made known through the usual scientific publications.—Mr. W. GUINNESS replied: The answer to the first part of the question is in the negative. The items collected from the several departments from which the total of £1,013,000 is made up are as follows:—

Admiralty, £983,000; War Office, £405,000; Air Ministry, £1,373,500; Ministry of Agriculture and Fisheries, £348,756; Board of Agriculture, Scotland, £51,585; Fishery Board of Scotland, £16,010, Forestry Commission, £7057; Mines Department, £1850; Department of Scientific and Industrial Research, £380,203; Scientific Investigation, £158,087; Ministry of Health, £1350; Scottish Board of Health, £100; Post Office, £53,000; Colonial Office, £16,000; Office of Works, £157,180.

These figures do not include expenditure in respect of salaries, &c., of administrative staff, except in the case of the Department of Scientific and Industrial Research.

In the case of the service departments (and to some extent of other departments also) it is impracticable to distinguish between expenditure on pure scientific research and that on technical research and experiment. The figures given include as far as possible provision of all such expenditure.

The normal work of the Government chemist entails a considerable though varying amount of research to which no definite proportion of the annual expenditure can be assigned, and nothing has been included in respect thereof in the above figures.

It is impossible to give the information asked for in the last part of the question, for the methods of pure and applied research are the same, the distinction between them being solely one of aim. All the research done by Government, the cost of which it is almost impossible to separate from that of experiment and development, is in its nature the same as that carried on purely for the advancement of natural knowledge.

Inquiry into Mental Deficiency.

Mr. HURD asked the Minister of Health what official expert investigation into the effect of mental deficiency upon the national life was now in progress; who were the investigators; and when their report might be expected.—Sir KINGSLEY WOOD replied: The Board of Control in conjunction with the Board of Education are about to undertake an inquiry into the incidence of mental deficiency; an inspector of the Board of Control has been detailed to carry out the investigation; it is estimated that the inquiry will take at least a year to complete; and it is not anticipated that any report will be available before that time.

Poison Gas in Warfare.

Colonel ENGLAND asked the Secretary of State for Foreign Affairs whether the League of Nations was considering the organisation of international action with a view to the prohibition of the use of poison gas in warfare; and, if so, what was exactly the position of such action.—Mr. A. CHAMBERLAIN replied: At the Arms Traffic Conference held at Geneva in May last, under the auspices of the League of Nations, a protocol was drawn up prohibiting the use of chemical or bacteriological methods of warfare. Twenty-five States have signed the protocol, which remains open for accession by other powers. It comes into force immediately on ratification as between those States which have ratified.

Colonial Medical Services.

The House went into Committee of Supply on a vote of £117,483 for the salaries and expenses of H.M. Secretary of State for the Colonies and H.M. Secretary of State for Dominion Affairs, Captain FITZROY in the chair.

Mr. ORMSBY-GORE (Under-Secretary for the Colonies)' referring to medical research, said that nothing was more important, because it was the doctor as much as the engineer who made Panama. Further work in combating tropical diseases was most urgent. It was a fallacy to suppose that only the white man found it difficult to live in the tropics; the black man found it equally difficult. In East Africa the birth-rate was very high, but the infant mortality was appalling. So far as he could get the figures he believed that anything from 400 to 500 per 1000 of the children born in many of the native areas died within the first year. He hoped shortly to visit West Africa and to issue a report on the progress there.

The vote was agreed to.

Pharmacy in the Army.

Mr. SCRYMGEOUR asked the Secretary of State for War whether he was now prepared to publish the report presented in 1922 by the Joint Committee on the subject of pharmacy in the army; and whether the Army Council were now willing to accept the modified requirements of the Pharmaceutical Society as presented by a deputation thereof to the Director-General, Army Medical Services, at the War Office in May, 1923.—Sir L. WORTHINGTON-EVANS replied: The report of the Committee referred to was published by the Stationery Office last year in response to the wishes expressed by Members of this House. As regards the second part of the question, the Army Council are satisfied that the requirements of the army in regard to pharmacy and dispensing are adequately met under present arrangements, and they would not be justified in incurring the expense of carrying out the changes advocated by the Pharmaceutical Society.

Mr. SCRYMGEOUR asked whether, seeing that there was agreement between the Army Medical Service Department and those who represented the pharmacy interests, it was not recognised by the Department that there should be an improvement on the lines of the modified recommendations.—Sir L. WORTHINGTON-EVANS replied that he thought the Service, as now administered, was an improvement on the past, and was adequate.—Mr. MAXTON asked if it was not proper to take the same care to safeguard the interests of soldiers as of the civilian population.—Sir L. WORTHINGTON-EVANS: Oh, at least as great.

TUESDAY, JULY 28TH.

Miners' Nystagmus.

The House went into Committee of Supply on a vote of £113,045 for the salaries and expenses of the Department of Mines.

Colonel LANE-FOX (the Parliamentary Secretary for Mines), replying after the debate, said nystagmus was a most difficult disease to deal with. A short time ago a very interesting report was issued by a committee of the Health Advisory Council, which pointed out that in this country we were more humane than in foreign countries, where they said that nystagmus was largely a nervous disease and that it was a mistake to encourage too many people to think they were suffering from it. The subject was now receiving very considerable attention, and constant research work was going on. A scheme was being elaborated between the Home Office and the Mines Department for dealing with the disease, and he hoped it would shortly be put into operation.

Pay and Allowances of the R.A.M.C.

Colonel DAY asked the Secretary of State for War if he was aware that the recent conference of the British Medical Association had unanimously decided not to print in their official publication any reference to the terms and conditions of service in the Royal Army Medical Corps, in view of what they alleged to be a breach of faith by the Government; and if he would, in view of attracting the best type of medical practitioner into the service, cause a revision to be made in the pay and pension allowances to officers of the Royal Army Medical Corps.—Sir L. WORTHINGTON-EVANS replied: I have seen in the press that the British Medical Association are stated to have adopted the resolution referred to. I recently conferred with the British Medical Association on the subject of the Royal Army Medical Corps, and I hope in the near future to be able to announce decisions on the matters which were then discussed.

Ex-Service Patients Sent to Switzerland.

Colonel ENGLAND asked the Minister of Pensions whether any tuberculous ex-Service men had been sent for their health to Switzerland to undergo the Spahlinger treatment or otherwise; and, if so, what were the regulations with respect to the selection of such cases.—Lieut.-Colonel STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: A few cases of pulmonary tuberculosis have been sent to sanatoria in Switzerland by the Ministry. The cases selected are those in which the department is satisfied, on the advice of their experts in tuberculosis, that treatment abroad is essential and that equally good results cannot be expected from the facilities available in this country. I am informed that the Spahlinger treatment referred to has, in fact, been given in certain cases as an incident of their sanatorium treatment, but the resulting evidence as to the value of the treatment has not, in the opinion of my medical advisers, justified the sending of patients at the public expense expressly for this form of treatment.

State-aided Housing Schemes.

Captain FRASER asked the Minister of Health how many houses had been built under State-aided schemes during the years 1919, 1920, 1921, 1922, 1923, and 1924, respectively, and in 1925 up to the present date; how many were now in course of construction; how many had been authorised; how many houses had been authorised under the Housing Act of 1923; and how many under the Housing (Financial Provisions) Act of 1924.—Sir KINGSLEY WOOD replied: The numbers of houses completed each year since 1919 in connexion with State-assisted schemes under the Housing Acts were as follows: 1919, 100; 1920, 15,711; 1921, 80,660; 1922, 89,001; 1923, 19,185; 1924, 52,730; and 1925 (up to June 30th), 44,293; total 307,689. Statistics obtained during the last 2¼ years show that in addition to this number 160,506 houses had been built by private enterprise without Government assistance in the period between Sept. 30th, 1922, and March 31st, 1925. The total number of houses authorised under the various Acts is 499,464, and on the 1st inst. 63,495 were under construction. Under the Acts of 1923 and 1924 the number of houses authorised to be built are 218,769 and 66,969, respectively.

Closing of Wandsworth Maternity Home.

Mr. VIANT asked the Minister of Health if he was aware that the maternity home of the Wandsworth borough council had been closed; that during the past 17 months there had been 87 cases of mothers suffering from abscesses of the breasts; that complaints had been made by patients and public bodies as to the lack of cleanliness and proper treatment; and that the services of all the staff had been dispensed with except the matron, who was retained and receiving wages as usual; and, in view of these facts, would he institute an inquiry.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative, and to the third part in the negative. My right hon. friend has, for some months, been aware of the special incidence referred to in the question, but repeated skilled inquiry has, up to the present, failed to elicit the cause of this unusual condition. He is informed that the borough council who have made every effort to grapple with the problem have now decided to close the home temporarily and to give notice to the staff. My right hon. friend is suggesting to the council that a conference should be held locally, at which his department would be represented, in order to discuss future arrangements.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

TUESDAY, August 4th, to SATURDAY, August 8th.—PRINCE OF WALES'S GENERAL HOSPITAL (N.E. London Post-Graduate Hospital), Tottenham, N. Intensive Course in General Medicine, Surgery, and the Special Departments. Work will begin at 10.30 A.M., and continue until 5.30 P.M., except Saturday, when there will be morning work only (first week).—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations, illustrated by cases daily at 5 P.M. Tuesday, Dr. L. R. Yealland on Disorders of Coördination. Wednesday, Dr. E. W. Scripture on Speech Disorders in Nervous Disease. Thursday, Dr. E. D. Macnamara on Disorders of Posture and Gait. Friday, Mr. L. G. Brown on The Auditory and Vestibular Apparatus in Nervous Disease.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 3rd.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 3 P.M., Dr. Saunders: Medical Wards.

TUESDAY.—12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards. 3 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 12 noon, Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations of *the Throat, Nose, and Ear.*

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Appointments.

BRERETON-BARRY, JAMES, L.A.H. Dub., has been appointed Public Vaccinator for Weymouth and Melcombe Regis.

REID, H., F.R.C.S. Eng., M.B., Ch.B. Liverp., Honorary Assistant Surgeon to the Royal Infirmary, Liverpool.

Ancoats Hospital, Manchester: TWINING, E. W., M.R.C.S., L.R.C.P. Lond., Honorary Radiologist; WELLS, C. ALEXANDER, M.B., Ch.B. Liverp., Resident Surgical Officer; ROBERTSON, MAURICE C. G., M.B., Ch.B. Aberd., House Surgeon; WOOD, KENNETH W., M.B., Ch.B. Manch., Assistant House Physician.

Certifying Surgeons under the Factory and Workshop Acts: KILLARD-LEAVEY, M. E. P., L.R.C.P. Lond., M.R.C.S. (Barnstaple); SOUTHERN, W. G., M.B., Ch.B. Manch. (Broughton-in-Furness); MOLLOY, H. H., M.D. Dub. (Helsby, Chester); MCDONALD, J. R., M.B., Ch.B. Edin. (Durham).

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Sen. Res. Surg. £330. Jun. Res. Surg. £300.

Barnsley and Wakefield Joint Sanatorium.—Asst. Tub. O., &c. £450.

Birmingham, Highbury Group of Hospitals.—Jun. M.O. £350.

Bristol, Cossham Memorial Hospital, Kingswood.—Res. M.O. £150.

Cairo, School of Dental Surgery.—Supt. and Lecturer in Metallurgy, &c. £E.900. Lecturer in Surg. £E.480. Asst. Lecturer in Surgery. £E.300. Lecturer in Mechanics. £E.180.

Chichester, Royal West Sussex Hospital.—H.S. at rate of £200.

Jersey General Hospital and Poor-law Infirmary.—Res. M.O. £200.

Hull Royal Infirmary.—Cas. H.S. at rate of £130.

Leeds Public Dispensary—Jun. Res. M.O. £150.

London School of Hygiene and Tropical Medicine.—Research Studentships in Tropical Med. £250.

Manchester, Ancoats Hospital.—Pathological Registrar. £100.

Mount Vernon Hospital, Northwood, Middlesex.—*Surg. Laryngologist.*

Pietermaritzburg, Grey's Hospital.—Male H.S. £500.

Royal Chest Hospital, City-road, E.C.—Asst. Tub. O. £550.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. £150.

Royal Northern Hospital, Holloway, N.—Anæsth. £10 10s.

St. Mary's Hospital, W.—Cas. H.S. at rate of £100.

Sudan Government, Wellcome Tropical Research Labs., Khartoum.—Asst. Bacteriologist. £720.

Sudan Medical Service.—Medical Inspectors. £E.720.

West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—Sen. H.P. at rate of £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment for Certifying Factory Surgeons at Wrotham, Kent.

Births, Marriages, and Deaths.

BIRTHS.

COLLINGWOOD.—On July 26th, at Marlborough-hill, N.W., the wife of Prof. B. J. Collingwood, O.B.E., M.D., of a son.

DOUTHWAITE.—On July 21st, at "Carlingford," Worthing, Sussex, the wife of Dr. A. H. Douthwaite, of a daughter.

HAMMOND.—On July 23rd, at "Penmorva," Harrow Weald, to Norah, wife of A. G. Hammond, M.R.C.S., L.R.C.P.—a daughter.

NIXON.—On July 25th, at 7, Lansdown-place, Clifton, to *Doreen G. C. Nixon, M.R.C.S., L.R.C.P., wife of Dr. J. A.* Nixon, a son (Gervase John Mapletoft), who only lived an hour, and a daughter.

RANKIN.—On July 24th, at Shubra, Boxmoor, Herts, the wife of T. Thomson Rankin, M.D., of a daughter.

MARRIAGES.

REYNOLDS—STEELE.—On July 22nd, at St. Paul's, Knightsbridge, Captain William Leonard Eliot Reynolds, M.C., *R.A.M.C., to Margaret Joan Pattison*, only daughter of Mr. and Mrs. W. R. Steele, of Farnham.

DEATHS.

BEATON.—On July 21st, at Highbury New Park, N., after a short illness, Robert Milne Beaton, M.B., C.M., J.P., aged 71.

BOWEN-HOGG.—On July 24th, at Stranraer, St. Peter's-road, St. Margaret's-on-Thames, Richard Bowen-Hogg, M.R.C.S., in his 70th year.

HENDRIKS.—On July 17th, at Bicester, Oxon, after a short illness from septic poisoning, Cecil Morgan Hendriks, O.B.E., M.B., M.R.C.S., in his 70th year.

RUDDUCK.—On July 22nd, at West Mersea, Essex, John Burton Rudduck, M.R.C.S., L.R.C.P., late of Assam and Morocco, aged 72 years. Husband of M. M. Peraton Taylor, late of Palestine and Morocco. Buried at West Mersea, July 25th.

WATSON.—On July 22nd, at North Bar Within, Beverley, of pneumonia, Walter Geoffrey Watson, B.A. Camb., M.R.C.S., L.R.C.P., in his 39th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1925.

THE Index and Title-page to Vol. I., 1925, which was completed with the issue of June 27th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Notes, Comments, and Abstracts.

POISONING BY SHOE DYES.

CASES of poisoning by anilin and nitrobenzene used in the various dyes for staining boots and shoes have not received much attention in this country, possibly because of their very rare occurrence, but the symptoms produced are alarming and may even prove fatal; hence a knowledge of this form of poisoning is necessary. Dr. C. W. Muehlberger has collected 47 cases from the literature and added nine recent cases occurring in America to form an interesting review of the whole subject.[1] Cases of poisoning following the splashing of anilin or nitrobenzene on the skin have been recorded,* painters using anilin-containing paint have been affected and certain cosmetic preparations for the hair containing this substance have also been known to give rise to dangerous symptoms. Even the anilin used to put a laundry mark on diapers has been known to produce effects in infants. Despite the fact that there appears to be some uncertainty about the toxic action of anilin and nitrobenzene, Dr. Muehlberger states categorically that even when perfectly pure these substances are intensely toxic and can be absorbed through the unbroken skin. The symptoms produced come on insidiously within a few hours of the wearing of the shoes stained with these products and consist of an intense cyanosis, often first noticed by the patient's friends, followed by collapse with weakness, dizziness, headache, and vomiting. If the patient be put to bed and the offending footwear removed, recovery usually takes place fairly rapidly, and no other treatment is necessary. At least one fatal case, however, has been recorded in which the autopsy findings showed that the liver was in a condition resembling acute yellow atrophy. Animal experiments have shown that anilin especially attacks the conducting tissues of the heart, giving rise to heart-block and various disorders of rhythm. In no case was methæmoglobin found in the blood although the cyanosis occurring in these cases is frequently ascribed to this cause. Chemical analysis of one particular brand of black shoe dye, known to have caused five out of the nine cases of poisoning reported in this paper, showed that it contained over 40 per cent. of anilin, and the only way to prevent the occurrence of these distressing cases seems to be the prohibition of the use of this substance and nitrobenzene in the manufacture of shoe dyes. Research as to suitable substitutes for these solvents for pigments which shall be non-toxic is said to be proceeding. Even these toxic dyes could be prevented, however, from producing ill-effects if the shoes thus treated were allowed to stand for 24 hours before being worn and if the custom of staining shoes "while you wait" on a person's feet, which appears to be common in America, were discontinued.

HEALTH CONDITIONS IN HONG-KONG.

A REPORT for 1923 gives the estimated population of the colony, including New Kowloon and the new territories, as 681,800, of whom 15,000 are non-Chinese. The birth-rate for the year was 6·97 per 1000 among the Chinese community (but this figure is wholly misleading, as it is impossible to register more than a portion of the births) and 23·03 per 1000 among the non-Chinese community, as compared with 6·25 and 22·84 for 1922. Deaths from malaria numbered 674. The deaths from plague were 130, as compared with 1071 in 1922. Small-pox deaths numbered 1141, of which all but 9 were Chinese. There were 4317 deaths from respiratory diseases other than pulmonary tuberculosis, as compared with 4863 in 1921, and 35 of these were among the non-Chinese community. Pulmonary tuberculosis claimed 1472 Chinese and 31 non-Chinese victims, whilst other forms of tuberculosis represent an additional 605 deaths, making a total of 2108, or 15·36 per cent. of the total deaths among the community. Beri-beri was responsible for 1270 deaths, as compared with 892 during 1922 and 526 in 1921. In the civil hospital, which contains 170 beds in 21 wards, 5455 in-patients and 28,297 out-patients were treated during 1923.

The total cases of malaria for all Government hospitals and the Tung Wa Hospital showed an increase of 160 cases, as compared with the year 1922. In the Tung Wa Hospital only Chinese are treated, but European as well as Chinese methods of treatment are employed in accordance with the wishes expressed by the patients or their friends. The lunatic asylum is under the direction of the superintendent of the Civil Hospital. European and Chinese patients are separated, the European portion containing 11 beds and the Chinese 16. 300 patients of all races were treated during 1923, and there were 3 deaths.

Incorporated in 1911, the University of Hong-Kong is a residential university for students of both sexes for the promotion of arts, science, and learning, the provision of higher education, the development and formation of the character of students of all races, nationalities, and creeds. The university includes the three faculties of medicine, engineering, and arts. The Faculty of Medicine provides a five-year course of study in the usual pre-medical and medical sciences, supplemented by clinical work in the Government Civil and Tung Wa Hospitals, leading to the degrees of M.B., B.S. The degrees of M.D. and M.S. may be obtained for post-graduate work. The degrees above mentioned are recognised by the General Medical Council for registration in Great Britain. With a view to better securing the maintenance of the desired standard—which in the Faculty of Medicine is that of an English university degree—external examiners are, in all faculties, associated with the internal examiners in all annual and final examinations. In the main buildings are housed the chemical, physical, and biological laboratories. Special medical buildings include schools of anatomy, physiology, pathology, and tropical medicine, erected at the cost of Chinese gentlemen resident in the colony.

AN IMPROVED CYCLE SADDLE.

OUR attention has been called to a cycle saddle made by Leatheries, Ltd. (Sampson-road North, Birmingham), at the suggestion of "Kuklos," cycling editor of the *Daily News*. The saddle, which viewed from above has the ordinary contour, is longitudinally divided into two saddles the width of the opening or slot being adjustable at either end. The object of the saddle is to prevent friction or perineal pressure, and the construction should prove useful to patients suffering from hæmorrhoids or after operations involving the perineal region. We are informed that a cyclist weighing 14 stone whose prostate was removed used the saddle for some months with comfort.

SOCIAL ORIGIN OF PROSTITUTES IN MOSCOW.

INQUIRY was made recently in Moscow into the social origin of prostitutes. As the inquiry had nothing to do with the police, and no names were asked for, it was considered that considerable reliance could be placed upon the answers —with one exception, those relating to venereal disease. This was universally denied, a state of things, of course, much too good to be true. S. Weissenberg summarises the replies in the *Zeitschrift für Sexualwissenschaft* for July. 642 satisfactorily completed questionnaires were obtained, the results of which were compared with those of an enquête at Kiev in 1913 on 236 registered prostitutes. Of the latter domestic servants formed 44 per cent., hotel employees 12 per cent., shop assistants 8 per cent., factory hands 6 per cent., only 10 per cent. coming from other social strata. Thus the very large majority was from the lower classes. The same phenomenon appeared, though to a less extent in the Moscow investigation, 60 per cent. of the subjects being of proletarian-origin. Domestic servants were only 22 per cent., thus half the former proportion, but this, independently of the variations to be expected with small numbers, could be wholly accounted for by the diminution in the total population of domestics between 1913 and 1925. This factor allowed for, they recruited the ranks of prostitutes to a greater proportional degree than formerly. In the minority were women of origins not previously met with and not always exactly stated; thus "daughter of a high official," "widow of a governor," "noblewoman," "countess," and so forth. The contingent from the nobility and land-owning classes amounted to 5 per cent., as also did those from the ranks of teachers and nurses. It is reasonable to suppose that the upset due to the revolution, with its exalting of the working class and humbling of their superiors, may have had a good deal to do with this modification of the social composition and personnel of prostitution. What also appears evident, thinks the author, is that social conditions cannot take all the blame of prostitution, which attracts those of a particular disposition.

HEDONAL.

To the Editor of THE LANCET.

SIR,—Will any of your readers say whether any experimental laboratory work has been carried out in this country with hedonal intravenously or otherwise in animals?

I am, Sir, yours faithfully,
JOHN DONALD.
Glasgow, July 20th, 1925.

Corrigenda.—In our account last week of the Ophthalmological Convention (p. 203) some remarks by Colonel A. E. J. Lister, I.M.S., on cataract, were wrongly attributed to Sir William Lister. In Mr. D. V. Giri's remarks, reported on the same page, the word "hypermetropic" should read "hypermature."

The Relation
OF
PARALYSIS AGITANS TO THE PARKINSONIAN SYNDROME OF EPIDEMIC ENCEPHALITIS.

A Lecture delivered in English at the Royal Society of Medicine on the Invitation of London University

BY DR. RENÉ CRUCHET,
PROFESSOR OF PATHOLOGY AND GENERAL THERAPEUTICS IN THE UNIVERSITY OF BORDEAUX.

WHEN in 1917, taking as my basis observations up to 1916 collected while with the army at Commercy, Verdun, Bar-le-Duc, I described for the first time "subacute encephalomyelitis," later to be known as "encephalitis lethargica," I believed it was a new disease. I remarked then the curious polymorphism of the disease, and specially noted several cases in which the immobile face existed from the first. It was already evident to me that the Parkinsonian appearance was in reality quite different from the disease associated with the name of Parkinson.

Later on, after the great outbreak of epidemic encephalitis of the winter 1919–20, certain manifestations, the so-called "Parkinsonian syndrome," were frequently observed. These manifestations were only the continuation of the early Parkinsonianism; others—much more frequent—constituted earlier or later sequelæ of the acute period of epidemic encephalitis. But in both my opinion was not changed, and I considered this so-called "Parkinsonian" condition to be quite different from paralysis agitans. That was the idea which, with H. Verger and Hesnard at the Société de Neurologie de Paris in June, 1921, I tried hard to get accepted. At that time we were almost alone in this opinion: now our conception is commonly admitted.

For that reason we have tried to find out why excellent observers had confounded the "Parkinsonian post-encephalitic syndrome" with paralysis agitans. We found that in these the symptoms which we have isolated under the terms "bradykinetic syndrome" were common to two distinct pathological states, but that in addition to these common symptoms there were others in which these two clinical types were clearly differentiated. On that account we will study, in the first place, the symptoms common to these two clinical types: the "bradykinetic syndrome," and, secondly, we will point out the phenomena particular to each.

BRADYKINETIC SYNDROME.

A syndrome is constituted by the association of several symptoms. The bradykinetic syndrome—as recently studied with Henri Verger in our clinical lectures at the Hospital St. André, Bordeaux[1]—consists in several essential phenomena, of which the most characteristic sign is slowness of movement. The other phenomena are: immobility, fixed attitude, kinesia paradoxa. After considering these we will say a few words on the muscular resistance.

1. *Immobility* is specially remarked in the face which is fixed and expressionless. It is often called the "Parkinsonian mask," although Parkinson has never mentioned it. "Charcot's mask" would be a more exact term. This immobility is found also in all the other parts of the body: there are no longer visible those thousand little movements or *tics* which are the personal expression of individuality, or underline the course of thought. To the expression of life has succeeded the fixed state of a doll, a mummy, or a waxen image.

2. The *attitude* is equally a fixed one and very characteristic. Generally the body is bent forward, the neck sunk between the shoulders, the trunk stiff, the arms slightly flexed on the forearms, with the hands brought towards the abdomen, the fingers flexed or extended, assuming what has been known as the writing position. Other attitudes are also met with; a lateral inclination to the right or left, an inclination backwards, and others, which vary with each individual. But whatever the attitude may be, one always recognises the condition by the aspect which is fixed, stiff, rigid, or "wooden"—as it is also called. (Fig. 1.)

3. *Slowness of the movements* is the most important sign. That is why we have designated this syndrome as the "bradykinetic syndrome" (of βραδύς, slow, and of κίνησις, movement). The term "bradykinesia" is entirely peculiar to us, and we have used it for the first time in medicine in 1900 in our "Traité des Torticolis Spasmodiques." This slowness of movement is specially striking in the features. The expressions (laughing, astonishment, fear, sadness, attention, &c.) all show a want of spontaneity (Figs. 2 and 3); the slow movement is remarked in speech, opening of the mouth, movements of the lips (as whistling, blowing, &c.), of the tongue, and in mastication and deglutition. All the movements of ordinary life are equally slow. Movements of the head and neck, shoulders, trunk and the limbs, as in walking, sitting down, rising up, stooping, turning, &c., all become stiff and automatic-like.

In acts more complex, as in using the fingers, this bradykinesia is still more noticeable. In drinking, eating, shaving, doing the hair, washing, dressing and undressing, sewing, knitting, rolling a cigarette, folding, writing, playing the piano, &c., patients take a much longer time than they did when in health. The same remarks apply to professional work. We have known electricians, masons, book-keepers, embroiderers, cashiers, typists, &c., who required eight or ten hours for the work they previously did in four or even two hours or less.

It is interesting to particularise the characters of this bradykinesia. The slowness has nothing in common with what one meets with in people naturally slow by birth or temperament. Thus, all these movements seem restricted and stiffened, without the thousand little gestures whose disappearance has already been alluded to in describing the immobility and attitude. For instance, in walking the characteristic automatic movements of the arms are wanting; and in writing or lecturing, eating or drinking, none of the gestures of attention or accompaniment are to be seen. It is important to specify, however, that all these movements are correct and perfectly coördinated, though slow. Then, the beginning of the act is never sudden: it seems delayed and to follow at an interval on the act of will which causes it. The longer the act goes on and the oftener it is repeated it becomes slower and slower in its execution. Then stops, of which the length seems to increase, are observed until complete arrest occurs. At last it happens that the movement which is being executed lasts longer than the will to go on with it. Thus it is that the patient who wishes to stop when walking, or who is suddenly told to stop, goes on, against his will, to make a few steps forwards. In walking backwards or sideways the same happens.

4. *Paradoxical Kinesia.*—The term was used by Souques in 1921, but the condition was known to Parkinson himself in 1817. The phenomenon consists really in this, that certain patients, only able to walk slowly and with difficulty, become at times capable of running. One of the two pathognomonic signs of paralysis agitans, as James Parkinson described it, is here indicated—the festinating gait—that is to say, following his words: "A propensity to bend the trunk forwards, and to pass from a walking to a running pace." These phenomena are classical and met with in all the descriptions, principally in Trousseau and Charcot.

A patient, quoted by Souques, who was incapable of making any movement whatever, could at certain moments cross one knee over the other. Incapable during several hours of answering or answering with a few words five minutes after the question was put to him, he could, at instants, speak easily. That is another instance to which Parkinson makes allusion when he compares the failure of the will of the patient to effect an arrest of his running to the " volubility," " a similar affection of the speech, when the tongue thus outruns the mind." But these phenomena had passed completely unperceived in post-encephalitic bradykinesia till we in 1920–21 pointed them out for the first time. There is no question in the encephalitis of some limited movements which are always the same; the question is of various complex acts, executed in conditions which astonish the mind and constitute a real *activity of contrast*, of which I will speak later.

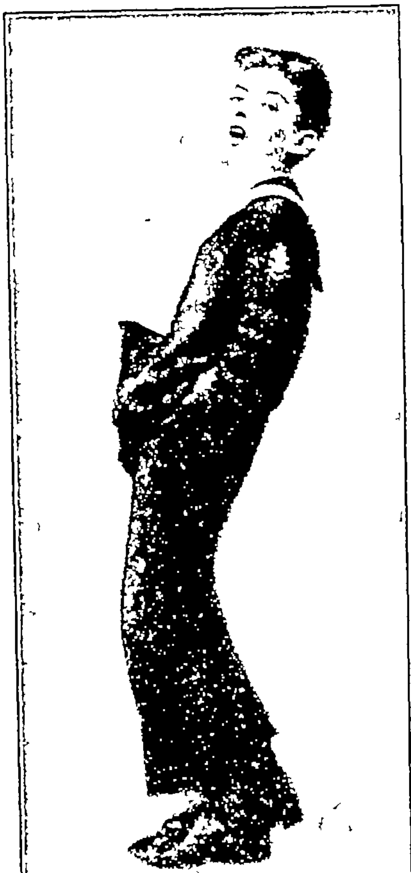
---

[1] Henri Verger and René Cruchet: Les États Parkinsoniens et le Syndrome Bradykinétique, Paris, 1925.

5. The four preceding symptoms are sufficient to characterise the bradykinetic syndrome. The study of *muscular resistance* is superfluous. It seems, however, that the authors who have specially described it have been the victims, with Charcot, of a preconceived idea. In considering the appearance of these patients, stiff and rigid and wooden, they have deduced an idea of rigidity; and as if that were not enough, others have made it worse and gone on to speak of hypertonus. Rigidity has come to be thought, since Charcot, the essential element of paralysis agitans. Tremor itself might not be present, and rigidity alone exist; these authors do not hesitate all the same to say that it is Parkinson's disease. Indeed, Parkinson himself would find it impossible to recognise in most descriptions nowadays the disease which bears his name. Tremor, for him pathognomonic, is not thought indispensable, while the rigidity, which he has never mentioned, is regarded as necessary and sufficient.

I do not hesitate to say that this description of Parkinson's disease is deplorable, because in this particular disease the rigidity is wanting, even when it is looked for. If these authors would take the precaution to tell the patient to remain absolutely passive and to oppose no resistance whatever, they would note that the movements are effected with freedom as in the normal state. If there be a muscular resistance, be it persistent as in lead-pipe, or intermittent as in cog-wheel, it disappears as soon as the first passive movement is ended. When the limb is again at rest, and you want to make it move, this resistance reappears, but disappears again with movement, and so on. Even in typical cases of Parkinson's disease, if it be not too advanced, this so-called rigidity is absent. Thus, the last Parkinsonian case with tremor which I saw some months ago was a man 68 years old; it was enough to put his superior or inferior limbs in complete release, and it was possible to move them in all directions without perceiving the least muscular resistance.

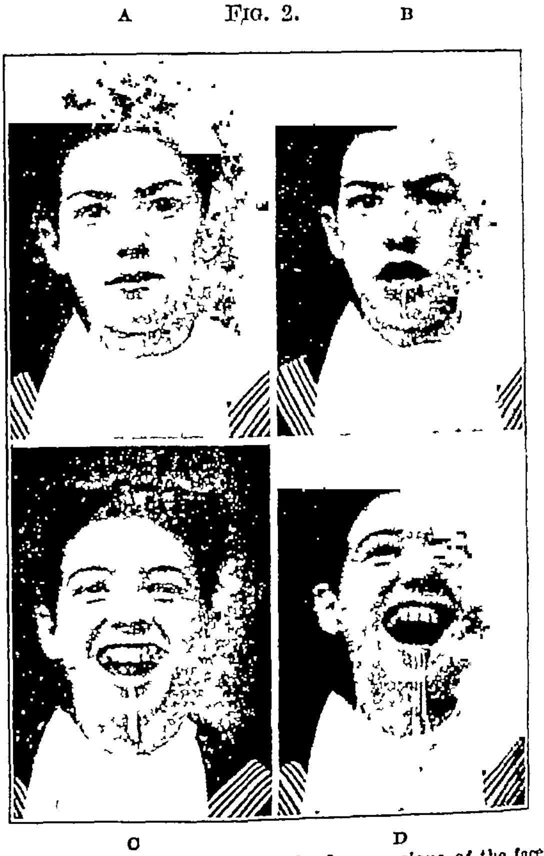
FIG. 1.



Postencephalitic bradykinetic attitude. Bent backwards, mouth half opened.

With old cases of Parkinson's disease, evidently, as with certain post-encephalitic bradykinetics, one may observe hypertonus and even the sort of rigidity which recalls the special contracture of spasmodic infantile diplegia; but those are patients ill for a long time. Even in those cases, not even in those of long standing, and often never, rigidity exists such as we have already shown it with Henri Verger.

FIG. 2.



The same boy as in Fig. 1 with fixed expressions of the face. A, Serious look with shut mouth. B, Commonly the mouth is open and saliva is trickling out. C, Smiling expression with salivation. D, Laughing, with still more salivation.

Thus reduced to its most simple expression the bradykinetic syndrome is common to a certain number of morbid states, amongst which, without speaking of the Parkinsonian disease and epidemic encephalitis, one may mention certain chronic deforming rheumatic cases, progressive lacunar cerebro-sclerosis, disseminated sclerosis and pseudo-sclerosis, dementia præcox, spasmodic infantile diplegia, chronic chorea, athetosis, chronic myoclonus, and myorhythmia. In 1906 we already showed that bradykinesia can become spasmodic and be associated with certain forms of spasmodic torticollis.

But we will limit our study to the particular characteristic signs which constitute the bradykinetic syndrome, as seen in Parkinsonian disease and in epidemic encephalitis.

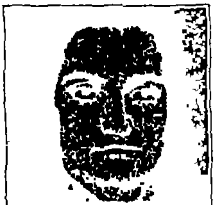
PARKINSONIAN BRADYKINESIA.

In Parkinson's original description the characters of bradykinetic syndrome are noted. The study of slowness of movements and of immobility, specially of the face, is, however, not particularly indicated. Has it been forgotten? Or is it not rather that the enumeration of these phenomena did not seem necessary to the author? As it is a question, following Parkinson, of paralysis, these troubles of the least motor activity, so common and so evident, are they not, by definition, a part of the clinical picture? James Parkinson insists only on the particular evolution of this paralysis; he shows its mode of progression, so different from ordinary paralysis, in which "abolition or diminution of voluntary muscular action takes place suddenly." Here, on the contrary, "the diminution of the influence of the will on the muscles comes on with extreme slowness."

There is a quite singular evolution for a paralysis according to the ideas of that period. Parkinson remarks it expressively. The movements of the face and all movements in general are diminished, "weakened," slackened; are these not evidence of a paralysis? Parkinson finds it needless to speak of it.

To return, two phenomena of a new kind strike him in this paralysis, first of all, and specially, the "shaking"; second, "a propensity to bend the trunk forwards." In this second symptom may be recognised the characteristic attitude of the bradykinetic syndrome. "This propensity to lean forward becomes invincible," as Parkinson says; the result being that the patient, "irresistibly impelled to take much quicker and shorter steps, and thereby to adopt unwillingly a running pace"—substitutes "running for walking," so as not to fall. There we find again the phenomenon of "kinesia paradoxa," already mentioned. And it is natural that it should have attracted the attention of a clinician like Parkinson, little accustomed to see paralytics running.

FIG. 3.



Young bradykinetic woman with the same scale of fixed expressions of the face—serious, smiling, and laughing.

But it is the shaking which gives to the Parkinsonian bradykinesia syndrome its essential and principal character; it is that which is the pathognomonic sign of Parkinson's disease, and so he incorporates it in the definition itself—"shaking palsy." That is why he studies this tremor with such care—an "involuntary tremulous action, in parts, not in action, and even supported." This shaking is the first manifestation of the disease. Most often it begins in one of the hands and arms, and attacks little by little other parts of the body. A sudden change of position, or walking, stops it for a short time. But the time comes when movements are carried out with more difficulty, whilst the tremor becomes incessant and increases in violence. At the same time, in a progressive manner, the trunk is almost permanently bowed; the patient can hardly run or walk any more; he is no longer able to feed himself, he masticates and swallows with difficulty; even the saliva is continually dribbling from the mouth, and ultimately he dies of extreme exhaustion.

Later works on the subject have added little to Parkinson's account; some details have been particularised in describing the shaking—as a movement like that of pill-rolling or cigarette-rolling. Authors have also laid much stress on the agitation, the instability of these patients, who can hardly keep quiet; but Parkinson had already noted this fact in a few words, when he remarked that to calm the incessant tremor which troubled them, "harassed by this tormenting round," as he says, they continually walked.

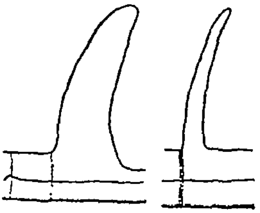
In short, the Parkinsonian bradykinesia is essentially characterised by its insidious onset, at an advanced age, its progressive evolution, its mental state (want of movement, irritability, bad temper); its late salivation, and specially its particular tremor which exists at rest and disappears in voluntary action.

POSTENCEPHALITIC BRADYKINESIA.

The bradykinetic syndrome is here quite complete; the general immobility and impassiveness of the face are striking, especially because we are dealing generally with young people. The fixed attitudes are equally remarkable, but more varied than in Parkinson's disease, where the bend-forward is especially characteristic.

Slowness of movement, rather neglected till we described it, has been studied with more precision than with the real Parkinsonian case, on account of the usual absence of tremor. We have noticed the delay in the beginning of movement, then the successive stops till a complete arrest ensues. All these phenomena have been remarked in the acts of ordinary life, and experimentally controlled, on myograms by H. Verger and Hesnard. (Fig. 4.) The modifications of handwriting, with progressive micrographic letters, are well known.

FIG. 4.



Myogram obtained after an auditory or visual test with a bradykinetic patient. On the curve to the left the reaction-time is longer than in that to the right, which is the curve of a normal man. The distance between the two dotted lines is wider on the bradykinetic than on the normal curve.

Reading is quite as interesting to study, as we have shown. The patient begins to read in that characteristic dull and monotonous voice; then a sudden stop occurs at the end of the third or fourth line. The eyes are obliged to go rapidly from the end of one line to the beginning of the next, and this movement does not take place immediately. Then it goes on, and reading continues, to stop suddenly again at the end of the line. But little by little, as the reading goes on, the stops are more and more frequent, every two lines, then, every line, and even, in the course of the line, sometimes in the middle of the word. The stops, first of all short, last longer and longer, the voice lowers, and comes to be hardly perceptible, and reading comes to a stop. In acts which require more complex movements, another very curious particularity is noted: it is the stopping of movement in motion, and that in the most uneasy positions. Thus, a spoonful of liquid remains near the lips, held in a sculptural attitude during several minutes; or a draught of milk, or a mouthful of food may remain in the mouth, without being swallowed.

One of my patients, while putting on his trousers, became all at once immobile and bent forward; another, when he wished to pick up something on the floor, bent down, caught the object, and after having lifted it a few centimetres remained for more than a minute in this bent position. Another one, standing, wishing to take his handkerchief from under the pillow of his bed, stretched *himself out on it and remained* immobile and fixed during three or four minutes, with the head forward and the hand held out, a few centimetres away from the desired handkerchief. A patient, quoted by Arthur J. Hall, "when brushing the hair, may raise the brush to the head and then progress no further." One sees in these attitudes, the catatonic perseveration, a truly singular phenomenon.

But it is the paradoxical kinesia which is chiefly remarkable. This activity of contrast, however curious, had passed completely unobserved till we called attention to it in 1920 and 1921. We have described several patients, who showed an inert, immobile and fixed aspect, and yet, all the same, at certain moments could play with a ball, or at battledoor and shuttlecock, or go up and down stairs, split wood with an axe, jump close-legged more than one metre high and three metres distance, even carry out evolutions on the horizontal bar. Others continued to motor, to cycle, play football, skip with a rope, to play the piano, violin, or brass instrument. I have seen three who seemed infirm and quite immobile in an armchair and who, all the same, began to dance in my consultation-room.

One of my patients, a brakesman employed in a railway company, at the arrival of the train in the station, came down from his car, shouted the name of the station in passing before every car, and then returned to his post till the next stage. Another, a man cook, whom they were obliged to help to dress and to eat, beat one day an excellent cream, to the great astonishment of those who surrounded him. He and his comrade, the brakesman, were both very skilful at the game with a cork, which consists in throwing down a cork covered with pennies, at 12 metres distance, with a quoit of the dimension of a guinea thrown with the right hand. They knocked down the cork each time, a rare performance for a normal man and all the more extraordinary under the circumstances.

These cases are now very well known. Arthur J. Hall has described how a "fine strong young man, whose immobile face, posture of limbs, and trotting gait are unmistakable, drove a three-ton lorry from Sheffield to London and back in three days, with nobody but a small boy with him. On another occasion, when leaving the out-patient department, he stepped on to the top-rail of the seat and jumped to the ground with the greatest agility." The same author has seen a young man cross the Strand opposite Charing Cross Station, at the busiest time of the day, by waiting for a momentary lull in the traffic, then trotting to the safety stage and stopping himself by clinging to the lamp standard. The second half of the passage was completed in safety, after a long wait, but he could only stop himself by clutching hold of a passing stranger, who thought the man had been taken suddenly ill, and escorted him to the railings. G. L. Thornton has noted that a young man, 29 years old, "in spite of his complaint of weakness in the legs, was able to jump over low obstacles and to run upstairs."[2] Finally, it is hardly necessary to point out the absence of rigidity, even less here than in Parkinson's disease. The clinical examination proves it; but the mere persistence of muscular activity, so considerable as to permit the execution of the preceding acts, would be enough to presume it.

That is for the bradykinetic postencephalitic syndrome.

But other complementary or added symptoms allow of a still better differentiation of the postencephalitic bradykinesia from the Parkinsonian bradykinesia. These are:—

1. *Tremor.*—The tremor is far from being the rule here, as in Parkinson's disease. It is, indeed, rare. In more than a hundred of my own cases I noted it ten times (one case in ten). Out of these ten cases, in three only did the tremor exist during rest and disappear during voluntary motion (Parkinson's type). In the seven other cases it did not exist during rest, and neither was it intentional, as in disseminated sclerosis. It appeared only in certain positions of fatigue, or else in movements which necessitated an effort, such as to write, to eat, to dress oneself, to shake hands, to carry a weight, &c., in which case its amplitude and intensity grew with the violence of the effort, to cease during complete rest.

A farmer, aged 53, was observed to have the tremor only in one position, evidently tiring: when he carried to his mouth a bowl or plate held with both hands, these were rapidly agitated by the tremor, and the liquid (coffee, milk, or soup) was upset. In the case of a typist, 26 years old, when she was asked to make a rapid movement of flexion of the right forearm on the arm, immediately the forearm began trembling at the speed of about seven jerks per second, with an amplitude from 2 to 8 cm. As soon as the patient changed the position of the limb the tremor ceased. But as these movements took place in many acts of ordinary life, such as eating, drinking, sewing, dressing, &c., it became a great nuisance for this young lady. Another character of this tremor, in distinction to the Parkinsonian shaking, is that it is not at all progressive. Several times we have noted it lessening with time; in three cases it completely disappeared in a few months, without ever coming back.

2. *Mental State.*—In contrast with the Parkinsonian bradykinetic, the postencephalitic bradykinetic patient is calm, peaceable, impassive, does not speak, asks for nothing, is willingly somnolent; he has an invincible repugnance to effort, even to the slightest movement. His greatest desire is to remain absolutely quiet, to have complete rest, rather in bed, where he will readily remain the greatest part of the day. To get up, to dress, even to remain sitting, is for him a fatigue which he would gladly avoid.

His intellectual state seems to slacken concurrently with his physical activity. His ideas are clear, his judgment intact, his memory retained, and his reasoning lucid; but to put his powers in use needs infinitely more time than before his illness. H. Verger and Hesnard have strikingly illustrated this bradypsychia or bradypraxis, or *psychic viscosity*. When these psychical modifications are not too marked, the activity is normal, but sensibly slackened; one would say that the patients have assumed a new personality.

An hotel-keeper, 56 years old, a woman, came to see me in February, 1923. She seemed a stolid person, with an expressionless face, speaking slowly and seldom, but perfectly clearly, her movements quiet and deliberate. She went on managing her business, attending to the cash and accounts. A stranger seeing this woman for the first time might very well have taken her for a person of quiet and reserved manner, calm and slow of speech and temperament, but, in fact, she had become so after encephalitis. Formerly she was a very active woman, always ready to laugh, quick and alert in movement and speech, and prompt in repartee. She knew herself to have changed, and complained of fatigue and lassitude. Indeed, her friends did not know her. Her personality had changed. I have seen other similar instances in my practice. Are they not curious and quite different from the proper Parkinsonian mentality?

3. *Onset.*—In contrast to the beginning of the Parkinsonian bradykinesia, "so slight and nearly imperceptible," writes Parkinson, "that it rarely happens that the patient can form any recollection of the precise period of its commencement," the onset of postencephalitic bradykinesia is nearly always easy to recognise. Somnolence, so-called lethargy, diplopia, frequent agitation with oneirism, even when there is no high fever, symptoms pointing to infectious disease, such as typhoid fever, toxic symptoms simulating botulism, enable us to fix the onset of the disease. The epidemic incidence is important. The greatest number of postencephalitic bradykinetic patients, whom we have observed, have had their attack between November, 1919, and April, 1920.

Age Incidence.—The average is about 60 in Parkinson's disease; the lower the age-period the rarer are the cases. On the contrary, with postencephalitic bradykinesia, the older the age-period the rarer the cases. Even children are frequently attacked—a quarter of the cases in my statistics.

---

[2] Brit. Med. Jour., Jan. 3rd, 1925.

4. *Evolution.*—While Parkinson's disease is fatally progressive, postencephalitic bradykinesia may get better, and even be cured. This depends on whether one deals with the early or the late form. The *early* form, of which I have observed several cases, is pretty often curable. One also often finds a regression or stabilisation at a certain stage, without a real return to the normal state. But most frequently the *late* form is met with. It appears between six months and two years, and sometimes later, after the apparent cure of the disease. In that case, unhappily, prognosis is less favourable. However, it is not necessarily progressive and fatal. I have known patients—for instance, the hotel-keeper of whom I have already spoken—where the illness advanced slowly to a certain stage and then remained stationary. With certain people, I have even noted phases of aggravation followed by phases of regression which finally allowed patients to recover an important part of their social activity. Others, on the contrary, become at length real invalids: incapable of moving, mute, immobile in bed, showing often the limbs fixed in flexion or extension, having even eschars on different parts of the body, and finally become extremely wasted and die.

5. *Other Differential Signs.*—We will pass rapidly in review certain other phenomena which serve to separate postencephalitic bradykinesia from Parkinsonian bradykinesia. Salivation is a very frequent and early sign in encephalitis, while it occurs late in Parkinson's disease. Pupillary troubles (inequality, slowness or loss of reaction to light and accommodation, miosis, mydriasis), exaggeration of knee- and ankle-jerks (without Babinski's sign), various changes in the cerebro-spinal fluid—especially hyperglycorachia—are particular signs of the postencephalitic bradykinesia.

A few words are necessary as to torsion-spasms, which are often met with in postencephalitic cases.

6. *Torsion-Spasms.*—In these different parts of the body assume extraordinary and tormented attitudes. I have quoted several cases, some more curious than others, but principally that of André V., whose detailed story is found in our "Clinics of St. André."

This youth, markedly bradykinetic, ordinarily would be found sitting with the head on the right, his chin on his breast, but the face turned towards the left, so that in order to look straight before him the eyes had to be turned upwards, the eyelids being raised to the utmost. The trunk was bent forward, so that only the middle of the back touched the back of the chair. Then the trunk would be bent little by little to the right side; the back, more and more rounded, would form nearly a right angle with the pelvis, the head and the trunk completely off the seat of the chair. In this incredible attitude, which lasted 10 or 15 seconds, it was astonishing how the patient did not fall; then, with a rather rapid movement he would resume his first attitude. And so on the whole day.

Facts of that sort are really very characteristic. But are they as new as is said? I do not believe so. Most authors consider that the neurosis of tonic torsion (Ziehen), or *dystonia musculorum deformans* (Oppenheim), or torsion spasm (Flatau and Sterling), descriptions which date back to 1910 and 1911, belong to the same clinical family as Wilson's disease or hepato-lenticular degeneration, which, too, was described for the first time in 1911 before the Society of Neurology of London. H. C. *Hall* (Copenhagen) thinks also that pseudo-sclerosis, studied by Westphal and Strümpell, which is but an atypic variety of disseminated sclerosis, is an analogous pathological state. Finally, neurologists have remarked how much these spasmodic phenomena, when localised, remind one of spasmodic torticollis.

SPASMODIC BRADYKINESIA.

It is only true to say that, in 1906, writing from the clinical point of view alone, and prior to the descriptions given by Ziehen, Oppenheim, Flatau and Sterling, S. A. K. Wilson, and H. C. Hall, we called attention to the same pathological entity, under the name of *spasmodic bradykinesia*—bradykinesia, because the movements were slow; spasmodic, because there were tonic or clonic (rhythmic or arrhythmic) jerks, added to the *bradykinetic phenomena.*[3] Since then I have observed other similar cases of which one, quite typical, occurred in 1907.[4] In short, as we said in 1906 and 1912, we meet with a generalised spasmodic syndrome, causing a rigid, fixed state with stiffness and general slowness of movements. All voluntary acts, whatever they may be, are constrained and slowed: writing, walking, especially going downwards, gestures of the arms, head, and trunk. The execution of movements often exaggerates the spasmodic condition. Frequently, at rest, there are athetotic and choreiform movements of the extremities; muscular instability of all the parts of the body; evidence of vasomotor troubles (sweating or excessive redness of hands, armpits, feet); alterations of speech, which is slow, stammering, and difficult to understand. And we added: "One cannot say that it is chorea, athetosis, paralysis agitans, Little's syndrome, disseminated sclerosis, tabes, Thomson's disease, or spasmodic wry-neck. Without doubt certain symptoms recall some of these diseases, but in themselves they are not sufficient to bring them under any one of these categories. That is why I proposed to name them *spasmodic bradykinesia.*

There is a perfect concordance between the views of these authors and those which we put forward about 20 years ago. Even then we already recognised that these curious states were not the real Parkinson's disease. The discovery of epidemic encephalitis, increasing considerably the number of these bradykinetic forms and their spasmodic varieties, formerly regarded as exceptional, has but confirmed our conceptions. It has allowed us in the meantime to study them better and to observe that the spasmodic state was, in most cases, but secondary, and not essential to the real bradykinetic state. These torsion spasms take place with the *associated forms* which unhappily always complicate, in medicine, the pathological descriptions.

Epidemic encephalitis, more than any other illness, on account of its polymorphism, is predestined to share in this confusion of classification. In our first article of 1917, the earliest to appear on this disease, we had already, founding on our personal observations, shown the diverse clinical forms it could take. We have already indicated the most typical and simple varieties, avoiding the associated forms. It is that same method which has guided us in the statements we have just made.

MORBID HISTOLOGY OF THE BRADYKINETIC SYNDROME.

The morbid histology of acute epidemic encephalitis is to-day well known. The first case, of which the definite histopathology was made out, goes back to April, 1917. It was one of my patients who died in Bar-le-Duc, near Verdun, and my colleague Anglade (Bordeaux) examined the microscopic lesions. He was immediately struck by their resemblance to the histologic lesions of hydrophobia and poliomyelitis in the mesencephalon, both due to filter-passing virus. Now, we find these figured in all the books and, particularly, in the remarkable work of Arthur J. Hall on epidemic encephalitis. I wish here only to consider the lesions connected with the Parkinsonian syndrome. I will not speak of the constant lesions of nerve-cells which are greatly altered in the same manner (reduction, atrophy, destruction), either in the cerebral cortex, hind-brain, grey nuclei, or in pons varolii, peduncles, and anterior horns of the cord. I desire simply to emphasise the curious property of the pyramidal cells to be intensely stained by histological dyes. Also I must add, and it is very important, that the lesions are destructive, insular, unsystematised, and especially marked in the locus niger.

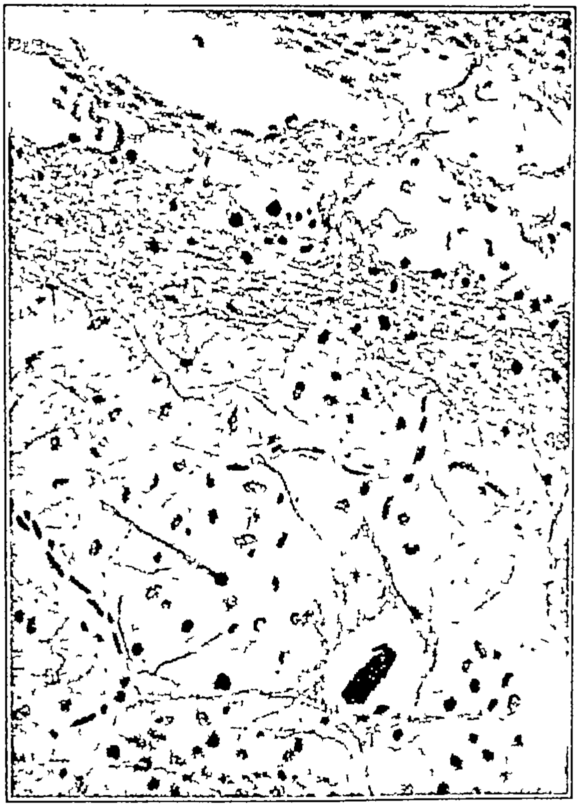
Anglade explains certain forms of Parkinsonian postencephalitic lacunar sclerosis by a neuroglia sclerosis. It is quite an original point of view. In fact, here (Fig. 5) it is not the adventitia of arteries which is involved as it is in the classic lacunar arteriosclerosis. The vessel remains intact; but around it the thick wall of glia cuff is losing, little by little, its cellular elements and crumbles away and falls down. Lesions of the locus niger are very intensive, there being almost total destruction of ganglion cells, which are phagocyted by glia cells. The pigment disappears in the substantia nigra and is absorbed by glia cells. Neuroglia fibrils are not very thick, but are always of the *insular* form, which is the chief character of the histopathology of epidemic encephalitis. There are no lacunar lesions in the aqueduct of Sylvius, red nucleus, and locus niger. But, nevertheless, the lesions are very important.

FIG. 5.



One can see the glia wall, and in the middle of it, the glia cells and fibrils falling down: that is the first stage of the special Parkinsonian postencephalitic lacunar sclerosis.

CONCLUSIONS.

We have studied the bradykinetic syndrome in its elementary form; then we have shown that the additions found in the Parkinsonian and postencephalitic types mark them out as original diseases, perfectly differentiated. From what we know of the diffusion of the encephalitic virus over nervous centres, it is easy to understand that it may give birth in certain cases to the true Parkinsonian type—2 or 3 per cent. in our statistics. But this simple statement shows how rare the syndrome is.

Equally we can well conceive the association of the Parkinsonian and postencephalitic type, as we have seen a few cases. But it is only an associated form, which must necessarily be divided in two essential types, if we will talk about it in a good medical sense. That is why, after all, we always return to consider separately the Parkinsonian and post-encephalitic bradykinesia. We take a firm stand on the sure ground of clinical observation; for anatomical findings, however interesting they may be, do not yet permit us to localise in a certain and definitive way the lesions which cause the bradykinetic syndrome, and the two forms which we have studied.

But this is the true medical method, that of all great doctors in all times and in all countries, the one, in particular, of Sydenham. I do not believe that any better or surer has been discovered. It is that at least which we try to practise in the Bordeaux University.

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF MUSCLE TONE,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

BY S. A. KINNIER WILSON, M.D., B.SC. EDIN., F.R.C.P. LOND.,

PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE IV.

(*Concluded from p. 219.*)

TREMOR.

BY comparison with chorea and athetosis, tremor is a motor derangement of a vastly simpler character. It may be defined as a succession of similar movements at equal intervals—more prec more
or less regular, rhythmical, al
of a muscular group or groups

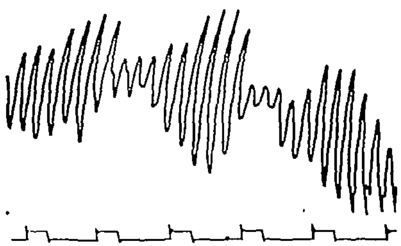
sometimes in a highly irregular way. Fig. 33 taken from a case of postencephalitic Parkinsonism (unilateral) exhibits this range variation clearly, and a fair degree of regularity in the variation. Irregularity of range excursion is seen in Fig. 34 (also from a postencephalitic case).

(3) *Rhythm.*—On the whole, the majority of organic tremors exhibit a rhythm from which they depart but rarely; the tremor is set in such and such a way, and modification seldom occurs. The rhythm of the hand movement in the Parkinsonian from whom the tracing of Fig. 35 was secured is almost mechanical in its perfection. Fig. 36 represents another Parkinsonian tremor, of equally clock-like rhythm but of variable amplitude.

FIG. 33.



Tremor in Parkinsonism. Variation of amplitude with a certain regularity.

(4) *Localisation.*—While theoretically any set of skeletal muscles and its opposite group may be seized upon by tremor, from the lips, or the fingers, to the trunk, the small muscles of the body are more particularly its seat. A mere catalogue of tremor localisations would serve no useful purpose; what is of greater interest is the curious way in which tremor will shift its incidence in a moment from one group to another. I have noticed this particularly [illegible] cases of progressive lenticular [illegible]ation, but it is a feature [illegible] a few cases of paralysis [illegible] For example, a flexor-[illegible]emor at the wrist will [illegible] one of a side-to-side [illegible] radial-ulnar deviation), [illegible]y to one of pronation-[illegible] and so forth. Again, [illegible]es will migrate in a still [illegible]nded fashion, leaving [illegible] or its distal segments, [illegible] the head or trunk, or [illegible]osite side of the body. [illegible]s reproduced in Figs. 37 [illegible] from a case of progressive [illegible] degeneration with a pro-[illegible] tendency of this kind for the tremor to [illegible]." Within a second or two of placing the [illegible] in position for a record of a wrist flexion-[illegible] tremor it shifted its incidence to the [illegible]-supinator mechanism, but returned a few [illegible] later to the original group, with reduced [illegible]ode (Fig. 37). On another occasion (Fig. 38) [illegible]hmical and seemingly unvarying pronator-[illegible]itor tremor altered its character as soon as [illegible]racing started, and eventually left the group [illegible]ether, passing to the biceps-triceps combination. [illegible] this variability or fluidity of distribution is sug-[illegible]ive not of a fixed structural disorder so much as [illegible], morbid process or state prone to develop itself [illegible]uch and such a muscular combination as a sequel [illegible] the interjection of some additional factor, the [illegible]ature of which will be discussed a little later.

A more remarkable illustration of this fluctuation is provided by a phenomenon which I have now observed some four times in cases of unilateral Parkinsonism, in each instance following epidemi encephalitis. The particulars of one case may b given.

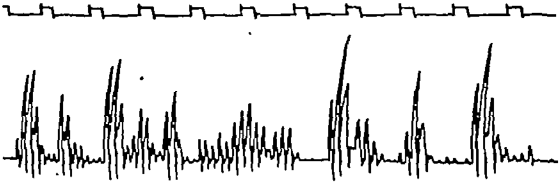
It was that of a youth of 10, with left-sided Parkinsonisr of a fairly severe character; his left hand and arm exhibite a typical rhythmical tremor which became particularl noticeable if the limb was unsupported, e.g., held out i front; support at all the joints either reduced it materiall or caused it to disappear. On the right (normal) side wa no sign of pyramidal or extrapyramidal disturbance. Th right arm could be held out by itself with absolute stead. ness. Now, when *both* arms were outstretched the lef at once exhibited marked rhythmical tremor of flexior extension at the wrist, and invariably, a second or tw later, the right outstretched and unsupported (norma hand went into a similar but finer tremor. Support applie to the left limb cut short its tremor, and within two c three seconds the fine right tremor would then disappe (Fig. 39).

Thus a limb in every objective respect apparentl normal developed a tremor whenever its fellow of th opposite side, rather severely involved in Parkin sonism, developed tremor; its tremor followed o the appearance of the Parkinsonian tremor, an ceased with cessation of the latter, yet both beginnin and end always occurred a second or two later in th case of the former. Its range was much finer, but it rate and other characters were identical. This pheno menon is of considerable interest, furnishing, as i does, additional proof of the fluidity of many organi tremors—a feature to be taken into account in respec of pathogenesis.

CONDITIONS INFLUENCING TREMOR.

We should derive a false notion of organic tremo if we contrasted it only with the known changeabl ness of so-called "functional" tremors, imaginin change to be typical of the latter and fixity of th former. Numerous "functional" tremors vary i minimal degree, while organic tremors can be an are influenced by a whole series of factors, as wi now be exemplified. When the back of the hand c a Parkinsonian patient whose tremor is in full swin is momentarily pricked with a needle the tremor ma cease for many seconds. Fig. 40 is the tracing fron such a case; at the arrow signal the dorsum of th moving hand was pricked for a moment and in thi instance something like ten seconds elapsed ere i recommenced. (The crescendo character of thi Parkinsonian tremor should be noted; the point i referred to below.) In a similar case of finer tremo the cessation thus produced lasted only for a secon or two. In still another case, of rather irregula tremor (Parkinsonian), the cutaneous stimulus effecte a transient interruption, followed, however, almos immediately by an exaggeration of the movement.

FIG. 34.



Parkinsonian tremor. Highly irregular amplitude.

Other forms of extrinsic excitation may produc an effect. At the arrow signal in Fig. 41 (idiopathi paralysis agitans) the sudden loud bursting of a paper bag filled with air caused no more than th briefest disturbance of the rhythmical tremor, bu sometimes the effect has been more pronounced Stimuli of an emotional sort may or may not hav their influence; attention in this respect is a dis turbing factor. I have always obtained bette results in the maintenance of tremor for recording purposes when the subject's eyes have been closed, to exclude visual stimuli. Not a few patients discover for themselves means of checking the involuntary movement, if only for a time. One of my patients could at once cause his tremor to cease completely by the simple procedure of supinating his affected forearm and hand. In another case, hyperpronation (“voluntary”) had precisely the same effect. (A cinematographic record of this phenomenon was shown.) Intelligent patients often work out for themselves some proceeding which has the desired result. This did not escape the acute observation of James Parkinson, who says in his essay that “the wearisome agitation is borne until beyond sufferance, when by suddenly changing the posture it is for a time stopped in that limb.” He cites the case of a Parkinsonian patient, who, “to illustrate his observation as to the power of suspending the motion by a sudden change of posture, being then just come in from a walk, with every limb shaking, threw himself rather violently into a chair, and said, ‘Now I am as well as ever I was in my life.’ The shaking completely stopped; but returned within two minutes' time.” In other instances, however, it vanishes for reasons as elusive as they are inconstant.

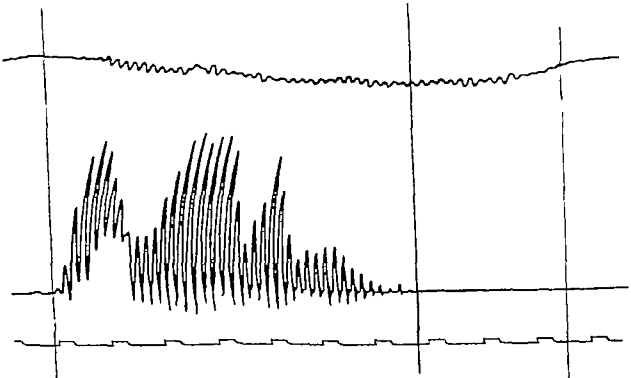
CLINICAL VARIETIES.

For years clinicians have recognised certain distinctions between the tremor of paralysis agitans and other striatal affections and that known as intention- or action-tremor, the latter being characterised by the fact that it begins only with “voluntary” innervation and increases with continuing action or “intention” up to a point, whereas the former is not so increased but may, on the contrary, diminish or cease. Further, action-tremor is seen only during “voluntary” motion, while the first variety occurs also when the limb is at rest. The supposed distinction has been recognised for centuries; it was already old when James Parkinson referred to it, quoting with evident approval the views of Sylvius de la Boe and of Sauvages, and indeed the germ of the idea is discoverable in the pages of Galen. In Parkinson's words: “If the trembling limb be supported, and none of its muscles be called into action, the trembling will cease. In the real shaking palsy the reverse of this takes place; the agitation continues in full force whilst the limb is at rest and unemployed; and even is sometimes diminished by calling the muscles into employment.”

Notwithstanding this authority, the distinctions are much more apparent than real; some cases of disseminated sclerosis, for instance, definitely show what I may call a “rest-tremor” as well as an “action-tremor,” while in progressive lenticular degeneration, as was demonstrated in my original monograph, the tremor is increased by voluntary action to a pronounced degree, though it is also prominent in the resting state. Thus combinations occur and invalidate distinctions. Moreover, in the finger-nose test the Parkinsonian limb at first often exhibits diminution or cessation of the tremor as it goes into action, yet after a moment or two of “rest” on the nose the fingers again become agitated, although the innervatory action of the limb musculature continues and the limb is certainly not “unemployed.” Clinical observation proves further that while in some instances a Parkinsonian tremor is checked by firm “voluntary” closure of the fist of the affected limb, in other cases the effect is transient and minimal, and the tremor redevelops notwithstanding the active “employment.” The exaggeration of the tremors of progressive lenticular degeneration by “voluntary” movement is strictly comparable to what obtains in disseminated sclerosis—an organic state to which "intention-tremor" is by some inaccurately, as I think, confined.

Reduction or cessation of tremor by supporting the limb—a reputed characteristic of action-, as compared with Parkinsonian, tremor—is met with nevertheless in the latter disease on occasion. *Its* occurrence has been shown in Fig. 39, taken from a typical case of the postencephalitic variety. On the other hand, the tracing of Fig. 42 is derived from a case of what I believe *to* be so-called idiopathic tremor, though I admit it is now exhibiting symptoms possibly suggestive of paralysis agitans. In this instance the tremor, at first seen solely during *unsupported* action of the limbs and vanishing instanter with support, is at length beginning to appear in the "resting state." On occasion, moreover, Parkinsonian tremors exhibit a crescendo feature (cf. Fig. 40), which is reminiscent of the similar crescendo of action-tremors.

FIG. 30.



Unilateral postencephalitic Parkinsonian tremor. Temporary appearance of tremor on the unaffected side (above). For details see text.

Finally, in this place, we may express doubt whether any hard-and-fast line can be drawn physiologically between a "resting" and an "active" state of muscle; action-currents in respect of these two differ only in a quantitative way. Clinically it seems a matter rather of degree of innervation than of differences in kind. From consideration of the data *the conclusion is, that the two types tend to run into each other and that neither is pathognomonic of involvement of a particular mechanism, radically distinct from that of the other.*

NATURE AND PATHOGENESIS OF TREMOR.

From its very nature we must allow that tremor can only be a phenomenon of a low physiological order, essentially different from the elaborate spontaneous movements of chorea and of athetosis. Tremor is purposeless and seems to have no "meaning," at least none easy of recognition, whereas choreic and athetotic action is subjectively purposeful *if none the less futile.*

(1) Various neuromuscular mechanisms are highly organised in the nervous system; others are organised in low degree or scarcely at all. Superior mechanisms *are capable of great variation*; inferior mechanisms are largely systematised. The more highly organised a mechanism, the lower is its physiological position. Spinal reflexes—e.g., the scratch-reflex—cannot be modified in respect of rate or character by variation of stimulus; cardiac and respiratory mechanisms are set at such and such a pace and, left to themselves, vary within narrow limits only. The fifty-a-second rhythm of motor nerve impulses *is practically* a constant. Instances of inherent neural and neuromuscular rhythms of minimal modifiability might be multiplied. By analogy, organic tremor is a *physiological phenomenon* of high organisation and low variability, for as we have seen its fundamental characters alter little and its average rate is fairly constant. It is constituted by a rhythmic discharge of neural energy, appearing in pathological states—a release-phenomenon set in a particular rhythm the innate nature of which, and its *raison d'être*, seem at present to be quite uncertain.

Clonus, similarly, consists of a rhythmical alternation in contraction of muscular groups, is a physiological state of a low order, falls into approximately the same rhythm as tremor, and undoubtedly tends *to manifest itself* when disease sets free inferior mechanisms. That tremor and clonus rates of contraction should not vary greatly from each other cannot be a pure coincidence, even though the anatomical cause of their respective releases be structurally different in each.

(2) This neuromuscular rhythm being *normally* held in check by inhibition and demonstrable only in certain diseased or abnormal states, the next point is whether for its appearance a particular condition of low motor centres, or of the muscles themselves, or both, is requisite.

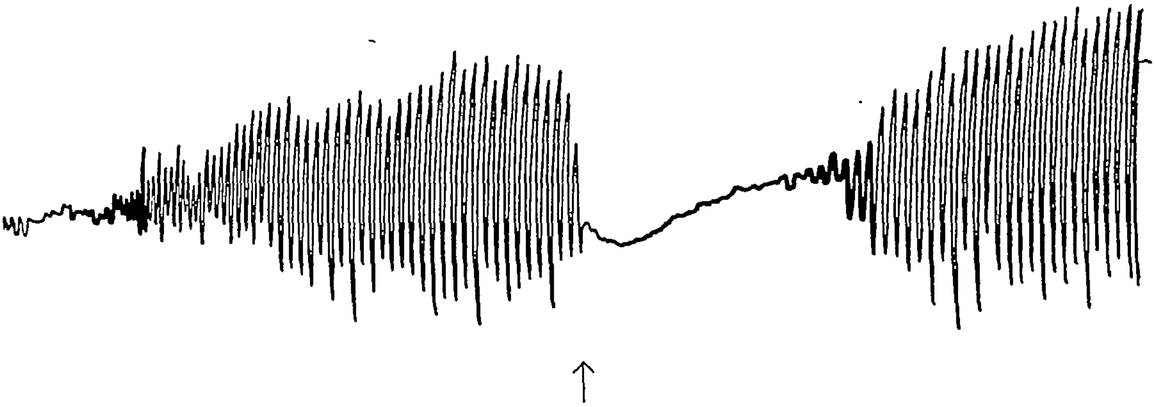
It is not found clinically in states of complete "paralysis." A paralysed and flaccid limb is never the seat of tremor. On the contrary, relative integrity of motor power is essential, and if as the result of an additional lesion a limb that has been exhibiting tremor is temporarily paralysed, one of the clinical concomitants is temporary disappearance of the involuntary movement. A fair number of cases are on record of the disappearance of tremor after an ictus of a hemiplegic kind, but it is important to note the absence of the tremor corresponds only to the time during which by diaschisis the *lower* motor neurones are *functionally* out of action; with some restitution of their proper activity, though the hemiplegia remains, the tremor will reappear. I have myself reported a case of this kind, in which syphilitic mesencephalitis was associated with the clinical symptom of tremor; a "stroke" led to cessation of the tremor, but only for a time which corresponded to the complete outfall of function throughout the corticospinal system; the movement reappeared after this acute stage, implicating *lower* motor neurones by diaschisis, was over. One hundred years ago James Parkinson observed a case of paralysis agitans where a sudden stroke paralysed the right side of the body; "*during the time of their* having remained in this state neither the arm nor the leg of the paralytic side was in the least affected with the tremulous agitation; but as their paralysed state was removed, the shaking returned." I am not aware of any recorded case where tremor has *permanently* disappeared after an ictus involving the pyramidal tract, and that alone.

(3) As a corollary, for the appearance of tremor *clinically the muscles implicated must be in a certain* state of tone. Atonic limbs do not exhibit the pheno-

menon; they may be hypotonic, however, and, as a fact, also, either ordinarily tonic, or hypertonic. We must therefore ask ourselves whether any relation or proportion can be shown to exist between the manifestations of tremor and of muscle tone.

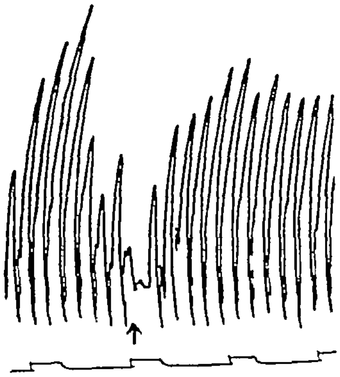
Of the common simultaneous occurrence of tremor and of muscle rigidity no question can arise; paralysis agitans is a frequent and convincing instance of the coexistence of tremor and rigidity; on the other hand, we have to explain the similar coexistence of tremor and hypotonia in not a few cerebellar cases. To take the former first: my studies lead to the conclusion that, clinically speaking, *those cases of Parkinsonism that are most rigid show least tremor, or tremor that is most limited in amplitude.* I have been able to convince myself of this interrelation by the frequent observation in postencephalitic cases, that with diminution of the rigidity by treatment the patient will likely pass through a stage in which the tremor becomes correspondingly more obvious. Several patients have made this observation independently and have commented on it. Conversely, tremor wide in excursion and sometimes almost violent is seen in cases where rigidity is at a minimum. Further, in any ordinary case of the syndrome those muscular groups which are more rigid (proximal segments) always exhibit less tremor than those that are less obviously rigid (peripheral segments), and the same remark is true in respect of lips, tongue, &c. Similar observations have been made for other striatal conditions such as progressive lenticular degeneration. Precisely those cases have exhibited the "wildest" tremors in which muscular rigidity has not been extreme.

FIG. 40.



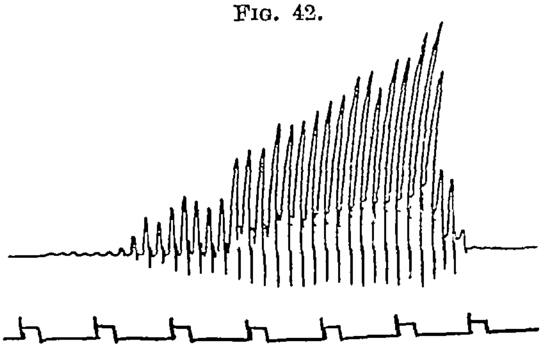
Parkinsonian tremor. Cessation after momentary cutaneous stimulus.

FIG. 41.



Parkinsonian tremor. Transient inhibitory effect of auditory stimulus.

FIG. 42.



Tremor (organic) produced when limb is unsupported and ceasing when it is supported.

Taking, next, cases where we have reason to suppose cerebello-mesencephalic lesions exist, rhythmical tremor resembling that of Parkinson's disease may be associated with a hypotonic state of the musculature. A number of such cases have been personally observed, and others have been made the subject of study by Holmes in his Croonian Lectures (1922). I am not able to cite any clinical instance of such tremor having been modified by subsequent alteration of the hypotonia through additional disease to a hypertonia, though were such a case to be studied and reported it would prove valuable.

According to a view expressed by Holmes, tremor is seen in hypotonic states only when "both the agonists and their opponents are contracted," as when a finger is to be held steadily say close to the nose without actually touching it. Diminution of postural tone allows the limb to oscillate, failure of fixation being followed by alternating contractions of certain groups of muscles and their antagonists. His explanation, however, only applies to cases where a hypotonic limb is being held "voluntarily" in such and such a position without support. Now we have seen similar oscillatory tremors to develop in limbs that are not hypotonic, as in some cases of paralysis agitans; and in the study of progressive lenticular degeneration, where also the musculature is hypertonic, analogous tremors have often been seen. Again, some cerebellar tremors of a regular, rhythmical sort are seen when no "active" innervation is taking place, as when a limb is hanging over a chair or over the edge of the bed (Holmes). That "voluntary" innervation is not a factor in the "spontaneous" tremors of resting limbs is of course obvious; nor is gravity a consideration, for the limb may be so placed as to counteract its action, yet the tremor continues.

Evidently, as tremors that are clinically indistinguishable can be seen to develop in limbs whose musculature is of differing degrees of tone—hypertonic or hypotonic—no explanation based solely on the state of tone can be applied universally. It is commonly understood, I think, that the rhythmical *alternating discharges of clonus are dependent on* enhanced muscle tone in the units concerned; an abrupt passive stretching effects a "stretching contraction," and this in turn will bring about a similar contraction in the antagonistic group, and so on almost indefinitely, so long as adequate tension is passively maintained. No explanation of this kind is applicable to the "spontaneous" tremors encountered by the clinician. Nor is any elucidation based on the presence or absence of "active" innervation sufficient to cover all the facts.

While, then, as regards diseased states characterised by both tremor and rigidity the degree of the latter is usually in inverse proportion to the extent of the former, we are not justified in claiming the tremor to be an expression of the muscular state *per se*. It is never found in the extremes of absolute atonia or hypertonia, but apart from these it may invade muscles whose tone varies within rather wide limits. Hughlings Jackson considered tremor and rigidity as it were opposite aspects of the same thing; he said that "tremor differs from rigidity, not fundamentally, but in degree," and explained the latter as being tremor "run together." He applied the idea in several other directions; for example, he spoke of a "diluted convulsion" as producing a condition "superficially like tremor." Again, he said that if by some magical process the movements made by a man in running were to occur simultaneously, "the result would be, not *any* movements properly so called, but an arrest of locomotion by a stiffening of the body into one attitude, a contention of all movements of locomotion." The applicability of this ingenious conception to the present question will be at once apparent to the reader. In a recent communication Walshe, however, declares the view that tremor and rigidity are interrelated to be "wholly untenable," although, curiously enough, he does not mention it as being due to Hughlings Jackson. That they are sometimes thus related is clear from their occurrence in inverse ratio, as illustrated above in Parkinsonian cases; but in other instances no such proportionate connexion is demonstrable.

(4) The fact that *tremor is not found clinically either in cortical or in spinal cases* I consider of prime significance. A lesion of the corticospinal system is not by itself sufficient to produce tremor, as everyone knows. As far as I am conversant with the literature, no case of tremor is on record pathologically in which the lesion has not involved grey matter situated somewhere in the vicinity of basal ganglia, mesencephalon, or cerebellum. In pointing out the occasional temporary cessation of established tremor by a corticospinal lesion, I do not admit the possible inference that, as Hunter states, "impulses through the cerebrospinal tracts are involved in the production of *spontaneous* tremor," if thereby the cortical arc is thought to be essential for its appearance. On the contrary, the evidence points in a quite other direction.

Brief consideration of the above-mentioned general localisation of the lesions associated with the appearance of tremor clinically at once suggests the existence there of some prespinal (*supraspinal*) centre or centres of control over a lower mechanism, whose activity expresses itself in the form of rhythmical alternating contractions of a given muscle group and its opposite, at a more or less set rate. Following the invariable rule, we say that since the lesions associated with tremor are destructive the supraspinal centre controls or inhibits, and when it is injured the lower mechanism is "let go." The alternations of tremor are, of course, an instance of reciprocal innervation, contractions of opposite muscles succeeding each other harmoniously in a never-ending series. We thus reach the conception that for tremor a particular condition of low motor centres is requisite, and that the state of tone of the muscles themselves is of less significance. None the less, it does not seem to be a mere coincidence that the levels of the lesions associated with tremor are also those from which alterations of muscle tone in large degree *arise*.

I must in the present instance leave on one side the data that might be adduced from experimental physiology to aid in specifying with greater exactitude the localisation of tremor-effecting lesions, as far as in the present state of knowledge we are able to do so. A brief excursus, however, may not be out of place.

Magnus has not seen tremor in any of his experimental "thalamus" animals, and comments on this absence of involuntary movement apropos of current striatal theories. Now in that animal *both* the corticospinal paths *and* the corpora striata are cut off from the parts further back (lower down)—an experimental state not in any way comparable to the lesions usually associated with the development of tremor in man. In fact, few if any experiments hitherto have satisfactorily reproduced the kind of case the clinician frequently encounters. That tremor, none *the less, is occasionally* producible by experimental methods is known from the work of Economo and Karplus, and of Lafora. In Graham Brown's stimulation experiments on the mesencephalon (decerebrate animal) tremor has been obtained in the red nucleus vicinity. I had the opportunity of seeing one of the hemi-decerebrate cats of Bazett and Penfield, and observed tremor in the advancing of the limbs on the affected side. The now rather older experiments of Ferrier and Turner on the superior cerebellar peduncle have lost none of their importance quâ the experimental production of tremor.

(5) Clinico-pathological evidence does not at present enable us to pronounce with certainty on the relative claims of the corpus striatum and the cerebellum (naming only two collections of grey matter) to constitute that tremor-controlling supraspinal centre which in view of the data here collected and the argument advanced we are justified in postulating. In former communications an attempt was made, possibly somewhat rigidly, to connect tremor with the lenticulo-rubro-spinal path. I have never doubted, and further pathological knowledge only serves to substantiate, the general conclusion formerly reached as to the localisation of the lesions underlying its appearance; their relative limits have already been specified. But a purely clinical study of the present kind cannot give us all *the material* requisite for final decisions.

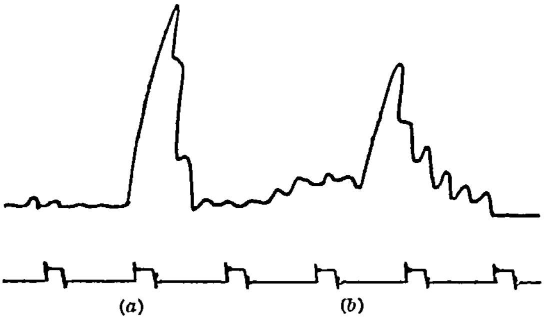
Viewed from another angle, however, as we have seen, tremor is to be considered the outcome of activity of a low-grade physiological mechanism released from a *non-volitional* prespinal centre, and it therefore becomes a matter of some interest to ascertain the relation of "volition" to, and its degree of control over, this *otherwise* decontrolled (say) mesencephalo-spinal mechanism.

THE PROBLEM OF "VOLUNTARY" CONTROL OVER AN "INVOLUNTARILY" DECONTROLLED MECHANISM.

The question, it will be realised, is a particular instance of an interesting physiological problem of which other examples readily suggest themselves. When a low-level centre is under the inhibitory influence of say two higher level centres of different kinds, one "volitional" and the other "non-volitional," what difference, if any, does *the* withdrawal of the latter control effect in the manifestations of the former control?

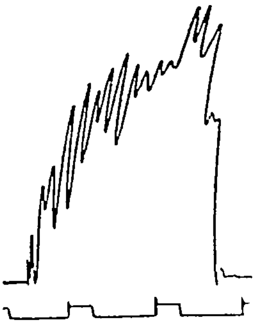
In the matter of tremor, "voluntary" influence is variable, fleeting, and not to be foretold, as it were. Thus during "voluntary" innervation of a tremor-exhibiting group of opposite muscles (say flexor-extensor) the current may suffice to blend the "involuntary" innervations into a tetanising contraction, of one or other muscle, as may be, with corresponding (relative) disappearance of the phenomenon for the time. Yet this is by no means constant, for in other instances "volition" augments and exaggerates existing tremor, or, alternatively, seems to bring out a latent state of this, existing as it were *in potentiâ*. Attention is directed to the accompanying figures. Fig. 43 is a direct tracing from the left quadriceps extensor cruris of a Parkinsonian patient with moderate rigidity and well-marked typical tremor. At (*a*) and at (*b*) "voluntary" contractions of the quadriceps were made, and during the ascent of the curve (shortening of the muscle) no tremor contraction is visible, though these begin again at once with decontraction, and continue. Now in the case of another equally characteristic example of the affection (Fig. 44) no such checking of the "involuntary" contraction is seen; on the contrary, it is traceable both in ascent and descent of the curve (contraction and relaxation of the extensor communis digitorum). Similar circumstances to those of Fig. 43 obtain in the record reproduced in Fig. 45, from another case (also left quadriceps). At (*a*) and (*b*) "voluntary" innervation serves to blend, or inhibit, "involuntary" innervations; at any rate, they are no longer to be recognised. If the reader will look back at Fig. 16, he will see how existing tremor is inhibited during the "voluntary" contraction of the extensors of the fingers and begins at once when the summit of contraction is reached, while during synchronous and equally "voluntary" (in the sense that the whole movement is one of "volition") decontraction of the extensors of the wrist the tremor maintains itself. The involuntary contractions blend with the "voluntary" contraction, but not with the "voluntary" relaxation that is going on simultaneously.

FIG. 43.



Parkinsonian tremor inhibited during "voluntary" contraction of affected muscles.

FIG. 44.



Parkinsonian tremor not inhibited during "voluntary" contraction of affected muscles.

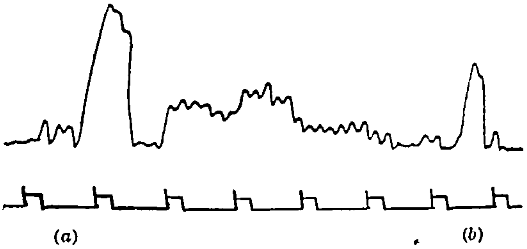
No other conclusion, I submit, can be drawn than that "voluntary" control over an "involuntarily" decontrolled mechanism is both imperfect and uncertain. It is unable to prevent the phenomena from making their appearances. The amount and maintenance of control are alike so variable that they preclude the possibility of similar fixed structural defects being responsible for the phenomena in every case. In a given instance it seems difficult to say what the interrelation of higher and lower mechanisms will turn out to be; tremor may be transiently inhibited by "voluntary" employment of muscles, or, on the contrary, it may accompany such action and refuse to be controlled—and this in different examples of the same disease. I believe considerations of this kind enable us to understand better the essential fluidity and variability of the clinical manifestations of tremor as described in preceding sections.

CONCLUSIONS CONCERNING TREMOR.

Summarising the results of the foregoing analysis of tremor, I may indicate some conclusions:—

Tremor cannot be due solely to a particular or specific manifestation of muscle tone, for it is met with in hypertonic, tonic, and hypotonic states; the fact of its being set in a rhythmical way at an average rate of fair constancy suggests it is the expression of an inherent property of neurocellular activity; its mechanism is of low physiological grade and is controlled by an ("involuntary") prespinal centre or centres at the general level of corpus striatum, cerebellum, and mesencephalon.

FIG. 45.



Parkinsonian tremor: "blending" of "involuntary" contractions during "voluntary" innervation.

"Voluntary" inhibition of this "involuntarily" decontrolled mechanism is essentially imperfect, inconstant, uncertain, and unsustained.

Tremor differs in fundamental characters from choreo-athetosis, above all in the fact that the law of reciprocal innervation is not abrogated in its case. Its underlying mechanism is quite distinct from that of the other group.

Tremor is an involuntary movement belonging to the old motor system (infracortical, subpallial), while choreo-athetosis is an involuntary movement of the new (cortical, pallial) motor system.

MOTOR FUNCTIONS OF THE CORPUS STRIATUM.

No pretence has been made in these studies to cover the whole field of striatal symptomatology, since they have been oriented from a somewhat different viewpoint. Much of the research, however, has an obvious bearing on theories of the function of that particular collection of grey matter, so that some discussion of our analyses of motor and muscle tone disorders is desirable in this connexion.

At the outset the serious obstacles in the way of reaching final conclusions were enumerated. Our uncertainty as to the diseases to be designated striatal (and solely striatal) on precise neuropathological grounds was specially emphasised, and hesitation in respect of these is still both natural and warrantable, notoriously as far as Huntington's and Sydenham's chorea is concerned. By comparison Parkinson's disease and progressive lenticular degeneration may be supposed to be less equivocally striatal.

Clinical analysis of various types of movement, and of the precise symptomatology of the two last-named affections, gives the following results. The assertions that they are characterised by "loss" of associated movements, reaction and defence movements, movements of coöperation, have been shown to be inaccurate. The view assigning a localisation of "automatic" movements to the corpus striatum is equally devoid of *foundation. The law of* reciprocal innervation holds for movement in striatal cases of the above group. Catatonic phenomena have no place in the syndrome. Still other points indicative of misinterpretation of alleged striatal motor symptoms have been recapitulated at various stages in the course of the lectures.

It may be of interest, perhaps, to refer now to one or two fallacies that have been noted in regard to movements and their meaning and localisation.

(1) One of the more serious is that which draws a hard-and-fast line between "voluntary" and "automatic" movements. No such line as a fact exists. "Automatic" movements, it will be granted, have been originally acquired, and, consequently, have at one stage contained a definite "voluntary" element. The child learns to walk. The supposition that this class of movement is at some unknown time transferred physiologically from a cortical locus to a striatal locus is devoid of any sort of probability and unsupported by any sort of evidence. However "automatic" walking and arm-swinging become, *they remain faintly "voluntary." As I have previously urged*, the gradation is not from "voluntary" to "automatic," but from "least automatic" to "most automatic," or from most to least "voluntary." After permanent lesions of the pyramidal system many acquired "automatic" *movements are* permanently lost. Were the intact corpus striatum the seat of these, they should exteriorise themselves via the lower motor neurone, which is not impaired *per se* in hemiplegias.

The other side of this question, so to speak, is that I have shown many cortical movements do not contain the element of "volition," but otherwise are similar in every respect to "voluntary" acts. Complex and elaborate tics are an instance in point, as are the motor phenomena of chorea. Before epidemic encephalitis became a clinical commonplace, tics were on their intrinsic clinical and ætiological characters with *entire* correctness attributed to disorder of cortical function. Some writers now appear to envisage all motor symptoms through an encephalitic *fog, arguing for* a striatal localisation of peculiarly elaborate movement-complexes because, forsooth, the virus of encephalitis has a striatal site in Parkinsonian cases! Such a claim can be made only at the expense of utterly ignoring the intrinsic clinical features of the movements in question. The corollary is logical, that if postencephalitic tics and *bradykinetic* syndromes are a sequel to striatal destruction, they must require for their activity non-striatal mechanisms. No hint is given as to where these are situated; but, assuming *from the complexity of the* movements *that* they are of cortical type, the inference would be that the corpus striatum is higher in the physiological hierarchy than the cortex itself, and that it controls *the latter*, so that when it is disordered cortical activity is "let go." This is *contrary to all our* conceptions of cerebral physiology.

The argument in preceding pages has pointed in the direction of a transcortical failure of *inhibition in the case of high-type* movements such as those of chorea, and the same argument is applicable to tics and similar *involved and intricate* movement-combinations. Continuing this line of discussion, I have already alluded to the *fact that movements* obtained experimentally from the motor cortex proper are not identical in all respects with the *movements* of "volition." *Physiologically*, they are of a lower class. The clinical phenomena of Jacksonian epilepsy bear out *this view. I have seen* individual muscles in pathological contraction from disease of the motor cortex, muscles that cannot be innervated "volitionally" in *the same way*. For example, I have seen in a Jacksonian case twitching of the right forefinger and thumb (a usual symptom, and of course not inherently different from "*voluntary*" movement of the same part) with *simultaneous twitching of the right levator menti alone*—this latter illustrates the present point. Again, I have observed distinct and prolonged *unilateral* twitching of the rectus abdominis in a Jacksonian case. *I do not require to adduce more* data to show that morbid processes can effect individual muscular contractions from the motor cortex, and that movements physiologically coupled can be dissociated similarly by *cortical* motor disorder. Further, interference with and derangement of the harmony of action of component muscular units in movement may occur at the cortical level and have been fully illustrated.

The Betz-cell anatomical area, then, is no more than a midway station between what I should prefer to call the true motor area of "volitional" action—viz., some much larger cortical region, possibly the frontal, and the lower centres of the pons, medulla, and cord. Clinical analysis of choreo-athetotic symptoms has shown us every variety of physiological dissociation and dysharmony in contraction of opposite groups, and converging lines of evidence have suggested such disintegration may take place at the cortical level.

(2) A second fallacy is common and insidious, *consisting in the tendency to attribute to lesions at* one physiological level symptoms which may in fact arise at more than one. If integration of neural levels is essential to harmonious motor activity the possibility of disintegration through a series of levels must be steadily borne in mind. I have illustrated the point in the case of such symptoms as micrographia, akinesis, poverty of movement, and catatonia. Since such symptoms may be caused by dysfunction at more than one neural level, no exclusive apportioning of the particular symptom to an anatomical lesion on one only can be justified. For several Parkinsonian symptoms I have shown above the probability of the intervention *of a "conscious"* factor. Not a little of the seeming akinesia follows from the patient's unwillingness to initiate movements that he knows will entail an effort. "Awareness" has been proved to play a part in the meagreness of the reaction- and defence-movements of some Parkinsonians. In these latter types the implication of cortical arcs is highly probable, since the selected excitations reach the sensorium If they are to be *set down to striatal activities alone*, and their absence to striatal disease, we are faced with the assumption that striatal function is a conscious function, for which it appears to me no evidence whatever can be adduced.

(3) A third source of confusion in a difficult subject arises from the variability of the symptoms called striatal at different times and under different circumstances, of which numerous clinical instances *have been provided in these lectures*. To identify symptoms with anatomical lesions thus becomes an unusually delicate and precarious business. As long ago as 1912 stress was laid, in discussing the pathogenesis of tremor and other involuntary movements, on the possibility of dynamic *modifications of function* without recognisable anatomical lesions. "Loss" of movement is a very elastic term. We have had more than one illustration above of the habit of arguing that "loss" of a movement justifies the supposition that the normal ganglion is the centre for precisely those movements which are considered to be "lost." What, then, is the anatomical state of the organ when movements are present at one time and absent at another?

I should like, in conclusion, to approach the problems that have occupied our attention from still another point of view.

(1) It is a priori highly improbable, and contrary to the dictates of common sense, that motor phenomena so conspicuously diverse and of such varying complexity as myoclonus, tremor, athetosis, chorea, tics, bradykinesis, torsion-spasm, micrographia, and

palilalia, should one and all be set down to disorder of striatal function. When we remember the histological simplicity and comparative structural homogeneity of the corpus striatum, in contrast with the greater dimensions, much more intricate cyto-architectonic complexity, and far wider connexions of the rolandic motor cortex, the idea of attributing all these disturbances to striatal disease, and of crowding corresponding "centres" into that ganglion, becomes nothing short of ludicrous. And we have seen that this Betz-cell area itself is physiologically inferior to a still larger motor region, which much cogent evidence suggests may be constituted by the frontal lobes. Too little attention has been devoted by striatal enthusiasts to the phenomena of apraxia or dyspraxia, to the movements of so-called coördinated epilepsy, to the syndrome of tonic innervation, to epilepsia partialis continua, and to other cortical and trans-cortical disturbances exteriorising themselves in motor symptoms, some of which at any rate are of a kind persistently attributed to affections of the corpus striatum.

In this connexion an anatomical look-round will help to correct distorted perspectives. The corpus striatum is a much simpler morphological structure than the cerebellum, simpler even than the optic thalamus, in which nuclear organisation has reached a stage unknown to its neighbouring ganglion. But no neurologist has hitherto assigned to disease of the cerebellum a heterogeneous miscellany of motor disorders of the kinds with which the corpus striatum is sorely overloaded. Some would reduce cerebellar function, perhaps with reason, to two or three elements, or even unify it completely. How, then, a relatively simple cell-fibre structure like the corpus striatum can mediate functions ranging from language (cf. palilalia) to innervation of muscle fibre (cf. myoclonus) is on the face of it inexplicable.

(2) Consideration of the intrinsic clinical features of some of the motor disorders put down to striatal dysfunction proves that under no circumstances can they be conceived of as resulting from defect or destruction of identical or similar mechanisms, for while some are physiologically of a high order others are of a low. Some can be understood only on the view that they contain elements belonging to the cortical series.

(3) My clinical studies have impressed me again with the belief, for which much support has been furnished here, that striatal symptomatology and striatal function must be comparatively simple; and they have forced me to the conclusion that the unwieldy and top-heavy symptom-complex which has gradually come to be erected on the ganglion must be rigorously stripped of non-essentials. In the preceding pages have been indicated the symptoms which must thus be discarded.

I have found no reason to modify in any important respect the syndrome originally enunciated, to the effect that the main features of disease of the corpus striatum consist of disorder of muscle tone regulation and the appearance of involuntary movements. These being "positive" symptoms, their causation is the freeing of non-striatal mechanisms from striatal control. The corpus striatum is a body one of whose functions is tone-control, for in its diseased state tone over-develops in the skeletal musculature generally; another of its functions is that of inhibiting the physiologically lower function of neuromuscular rhythm, for when it degenerates tremor is prone to make its appearance. I do not think, however, that in either respect its function is unique and exclusive of that of other centres of approximately the same order.

The "negative" symptoms of striatal disease would be constituted by actual loss or outfall of—what? Clinical analysis will not allow me to point to a single class of movement which is as a fact persistently and completely lost when the ganglion is out of action. We have had many instances of the ways in which different classes of movement are hampered as a sequel to striatal disease, but none of an absolute paralysis of any class. Fine movements of small muscles are seriously impaired—if the expression is preferred, "lost"; but then they are "lost" also in pyramidal disease. In this, as in certain other respects, gaps in our knowledge of striatal function remain to be filled.

Throughout these lectures no attempt has been made to assign separate functions to the composite parts of the whole ganglion, for in this region in particular speculation has completely outrun both clinical and pathological facts. On a previous occasion I have assembled the arguments against this special variety of striatal conjecture.

These studies were undertaken in the hope of making a further constructive addition to our knowledge of the basal ganglia, and if in some ways my results should seem rather of a negative or destructive kind I can only say that revision was sorely needed.

A STUDY OF THE FAMILY HISTORIES OF 300 PATIENTS SUFFERING FROM CHRONIC UPPER ABDOMINAL LESIONS.

By G. P. B. HUDDY, M.S. Lond., F.R.C.S. Eng.,
FIRST SURGICAL ASSISTANT, LONDON HOSPITAL.

The patients under consideration were all under the care of my two chiefs, Mr. James Sherren and Mr. E. C. Lindsay, at whose suggestion this investigation was carried out, and to whom I am indebted for permission to use the figures obtained.

The lesions present were of four types: Chronic gastric ulcer (simple), 95; chronic duodenal ulcer, 129; carcinoma of the stomach, 30; cholecystitis, 57; total 311.

In every case the diagnosis was definitely confirmed at operation, and, where necessary, by further pathological investigation. Some cases showed more than one lesion—hence the total number as shown in the table exceeds the number of patients.

Some patients with one or more of these upper abdominal conditions have given very interesting family histories, which show a remarkable tendency to the occurrence of these lesions in members of the same family. The following are striking examples:—

Case 1.—A glass packer, aged 50, was admitted into the London Hospital and transferred on June 20th, 1925, to Mr. J. Sherren. At operation three days later the diagnosis of duodenal ulcer was confirmed. The familial tendency is shown below.

Case 2.—A medical student, aged 24, admitted under Mr. Sherren, Dec. 12th, 1924, with a history of recurrent attacks of biliary colic. At operation the gall-bladder contained no stones, but showed evidence of chronic cholecystitis and was removed; the diagnosis was confirmed on pathological examination. The family history given is tabulated below.

Further examples will be quoted later. Of those investigated the most striking histories were obtained from those patients suffering from duodenal and gall-bladder lesions. The occurrence of such family groups as these leaves one with the undoubted opinion that there is a distinct family tendency to these diseases.

Familial Tendency.

Little has been written on the subject, but in 1921 there appeared an interesting article by Hurst,[1] who drew attention to the undoubted existence of such a familial tendency, and expressed surprise that the fact had been rarely recognised in the past. This same point was also emphasised by Sherren[2] in 1924.

An attempt was made to estimate this tendency by means of records of a long series of cases. 300 consecutive cases operated upon have been investigated, each patient being asked as to the family history, and any history of indigestion has been counted as a positive case. The term "indigestion" is, however, one which is very loosely used, and as in the majority of instances no exact diagnosis could be obtained—a control series of 100 cases, none of which patients suffered from indigestion or abdominal disease, was obtained. The results are shown in Table I.

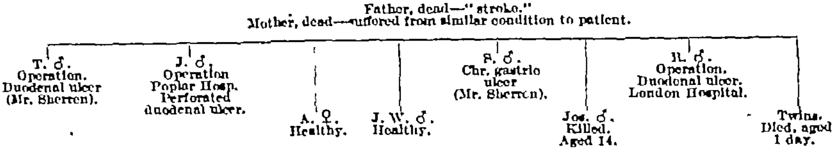
[2] Sherren, J.: The Lancet, 1924, i., 477.

CASE 1.—*Family History.*



CASE 2.—*Family History.*

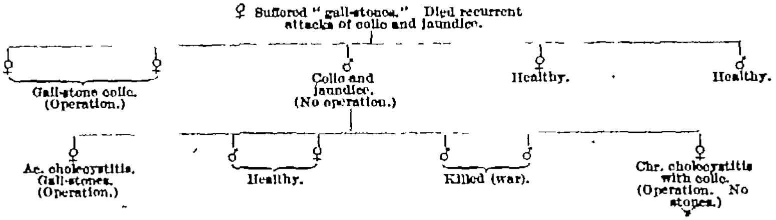


TABLE I.

—	No. of cases.	No. with indigestion.	Per cent.
Upper abdominal lesion ..	300	137	46
No history of "indigestion"	100	16	16

It is of interest to compare the frequency of these family histories in the various lesions, and this is shown in Table II.

TABLE II.

—	Total cases.	No. with indigestion.	Per cent.
Duodenal ulcer ..	130	56	43
Gastric ulcer	95	47	49
Gall bladder	57	24	42
Carcinoma	30	10	33

The points to be noted about Table II. are:—

1. The manner in which the percentage agrees in the first three groups.

2. The lower percentage shown in the carcinomatous cases. Carcinoma of the stomach may arise clinically in one of two ways—(1) primary, (2) secondary to a chronic ulcer. In carcinoma the familial tendency is not nearly as strongly marked; at the same time it should be noted that the percentage is higher than in the 100 "no indigestion" cases, and this is probably accounted for by the fact that in some of the cases the carcinoma arose on an old ulcer.

3. The gastric ulcer cases show the highest figure, although it has already been pointed out that the more striking histories are obtained in the duodenal and cholecystitis patients. This may possibly be accounted for in the following way—the duodenal ulcer tends to run in healthy families, whereas the gastric occurs as a rule in a family with a lower standard of general health, and so there is more probability of other extraneous causes of indigestion being present—e.g., ptosis.

The above figures confirm the fact already stated that there is a distinct family tendency to these diseases, though probably these figures, which are of necessity based on that extraordinarily vague term "indigestion," are of less importance than family histories, such as those recorded above in which the lesions were proved at operation.

Hurst in his article says:—

> "It is an interesting fact that I have never myself seen one member of a family in whom the presence of a gastric ulcer was proved, and another in whom a duodenal ulcer was certainly present. This suggests that the types of stomach which predispose to the development of gastric and of duodenal ulcers respectively are congenital, and either one or the other may exist in several members of the family."

Although Hurst states that he has never proved the presence of a gastric and duodenal ulcer in two members of the same family, such cases do undoubtedly exist; three such cases I quote below.

In Case 1 mentioned above it will be seen that three brothers were proved at operation to have duodenal ulcers, whereas a fourth one, who was also operated upon, had an ulcer situated on the lesser curve of the stomach. Two further cases are as follows:—

CASE 3.—On Nov 15th, 1923, a male, aged 30, was admitted and later operated upon for chronic duodenal ulcer. His mother had previously been operated upon for a carcinoma, which had supervened upon a chronic simple ulcer of the stomach.

CASE 4.—In February, 1925, a man of 40 was operated upon for acute cholecystitis; his father had previously been admitted and operated upon for a perforated duodenal ulcer.

The suggestion that the types of stomach predisposing to gastric and duodenal ulcers respectively are familial is probably largely true. There is, however, also probably a family tendency to certain infections which predispose to the formation of peptic ulcers; such are dental caries, as is shown below, and appendicitis, as mentioned by Sherren.[3] Now as probably in a family there are often the predisposing factors to both infection and the localisation of the ulcer, it is from members of these families that we obtain the most striking histories in which many suffer from one particular lesion—e.g., duodenal ulcer. If, however, the infection is the only common predisposing factor, then in one patient the lesion may be a duodenal ulcer, and in another member of the same family a gastric ulcer or gall-bladder infection.

The latter is illustrated in the first case mentioned, for in a family of four brothers, two, who were X rayed, had stomachs of different types—one high and hypertonic and the other low and sagging. In all the four brothers, however, there was a very definite history of marked dental caries preceding the onset of symptoms.

THE VALUE OF LIPIODOL IN THE DIAGNOSIS OF BRONCHIECTASIS.

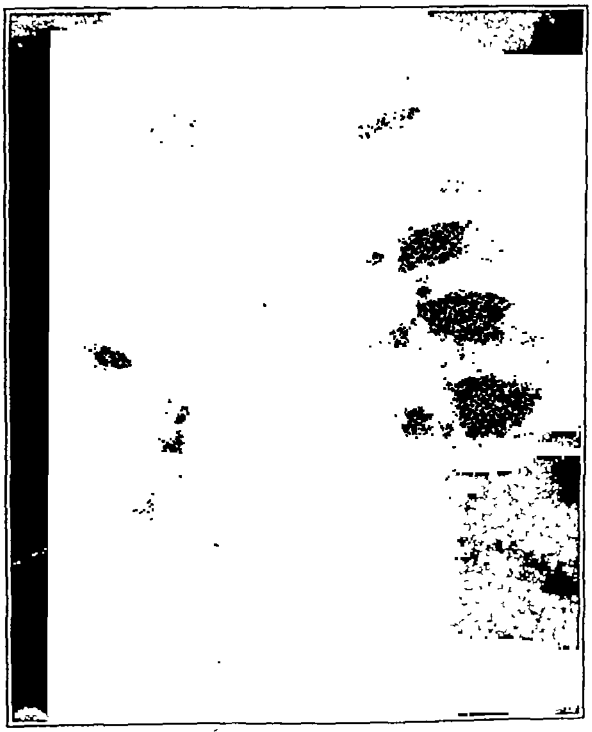
By L. S. T. BURRELL, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE BROMPTON HOSPITAL; ASSISTANT PHYSICIAN TO THE WEST LONDON HOSPITAL;

AND

STANLEY MELVILLE, M.D. BRUX.,
RADIOLOGIST TO THE BROMPTON HOSPITAL; HON. RADIOLOGIST TO ST. GEORGE'S HOSPITAL.

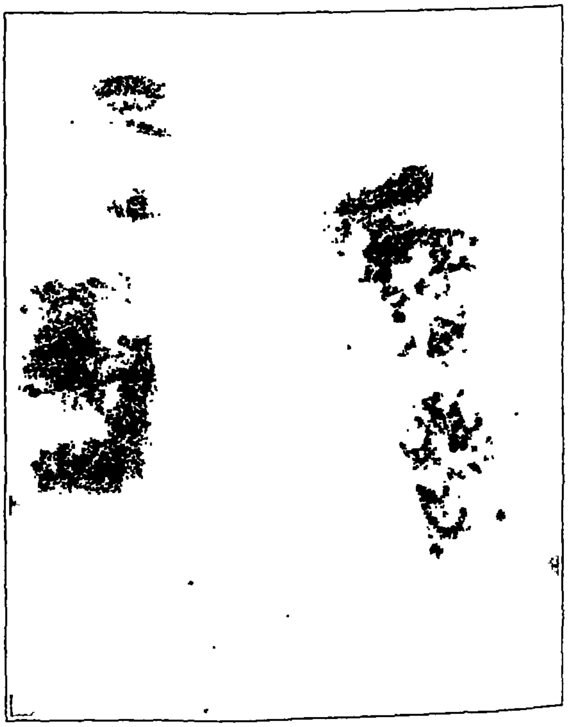
IN cases of unilateral bronchiectasis good results may be obtained by artificial pneumothorax or thoracoplasty. Usually, however, the disease is bilateral, and it is owing to this that the treatment so frequently fails. If an artificial pneumothorax is induced the quantity of sputum is reduced, but if there is *disease in the other lung* this reduction may be insufficient to afford the patient any real relief. The refills can then be stopped and the lung allowed to re-expand. If, however, thoracoplasty has been performed it is another matter.

FIG. 1.



Radiogram taken before injection of lipiodol. Left lung apparently sufficiently healthy to justify thoracoplasty.

FIG. 2.



Radiogram taken after injection of 20 c.cm. of lipiodol into the trachea. Condition of left lung contra-indicates thoracoplasty.

In one of our cases, a man with bronchiectasis had a large quantity of very foul sputum, was toxic, and running a high temperature. After an artificial pneumothorax had been induced he rapidly improved. He became afebrile, and what little sputum was left was no longer offensive. The collapse, however, was not complete owing to adhesions and areas of adherent pleura and, as so often happens in such cases, the lung was gradually drawn out and the pneumothorax cavity obliterated by the spread of these adherent patches. The symptoms returned and he became ill once more. As he had shown such great improvement when the lung was collapsed it appeared that there could be very little disease in the other lung, and he seemed to be an ideal case for thoracoplasty. This was performed and there was an immediate improvement, but unfortunately he contracted pneumonia and died.

In many cases, however, there is so much adhesion of the pleural surfaces that artificial pneumothorax cannot be induced at all, and it then has to be decided whether the better lung is sufficiently healthy to justify so serious an operation.

The following case illustrates the value of lipiodol *in helping to form an opinion as to the state of the* better lung.

The patient, a man aged 41, is a motor mechanic who enjoyed good health until February, 1922. He then had an illness which was diagnosed as influenza and pneumonia. Since that time he has had a cough and sputum, and every two or three months he has a febrile attack during which he brings up a quantity of offensive sputum. In October, 1924, he had an attack of dry pleurisy on the right side, and he went into a sanatorium. There were signs of fibrosis in the upper zone of the right lung, but although the sputum was repeatedly examined, no tubercle bacilli were found. At present his general condition is good between the febrile attacks and does not suggest any active tuberculous disease. He has great clubbing of the fingers. The right side of the chest is flat below the clavicle, and the percussion note is impaired all over the right side. Crepitations are heard at the right base and axilla, and there are a few below the right clavicle. On the left side expiration is slightly prolonged, the percussion note is resonant, and a few crepitations are sometimes, but not always, heard at the base. During the febrile attacks there is an increase of signs at the right base and axilla, but not on the left side. X rays (Fig. 1) show extensive fibrosis of the greater part of the right lung with interlobar pleurisy. The left lung shows only a general emphysema with some peribronchial thickening. Both from the clinical and X ray point of view it would appear that there is not sufficient disease in the left lung to contraindicate a right-sided thoracoplasty, if, as is probable, artificial pneumothorax cannot be induced. After injecting 20 c.cm. of lipiodol into the trachea with the patient lying on the left side, X ray (Fig. 2) showed very considerable disease at the base of the left lung, and on this account one could not advise a right-sided thoracoplasty.

We have seen more than one case where nothing was found in the better lung which seemed to contraindicate thoracoplasty, yet (after attempts to induce artificial pneumothorax had failed) the patient received no benefit from the operation, owing, no doubt, to disease in the other lung. The mortality from the operation for thoracoplasty is by no means negligible. Apart from this, it is a drastic method of treatment which cannot be lightly recommended, and lipiodol is undoubtedly of value in coming to a decision whether a case is suitable for the operation.

Reviews and Notices of Books.

THE CRIPPLED HAND AND ARM.

By CARL BECK, M.D. London: J. B. Lippincott Company. 1925. With 302 illustrations. Pp. xi.+243. 30s.

THE author of this book, a well-known Chicago specialist, has had ample opportunities of dealing with the various types of deformities of the hand and arm as the result of abnormal development, injuries and disease, and that he has made good use of those opportunities. As he states in his introduction, this work involves a great deal of plastic surgery, and, indeed, this book might well have been called "the plastic surgery of the upper extremity."

Part I. includes chapters on the normal anatomy and physiology of the part, and the rest of it is devoted to the consideration of crippled hands. In Part II. disturbances of the wrist, forearm, elbow, and upper arm crippling the hand are dealt with, and there are a few pages on artificial arms and a short chapter on technique. For the cure of webbed fingers, after describing some of the classical methods, including the impracticable one of Didot, Dr. Beck advocates the formation of a tunnel at the bottom of the interdigital cleft by means of a modification of Rochet's procedure for urethroplasty. For congenital defect of phalanges he recommends what is known in Europe as phalangisation of the metacarpals, but he seems to be unaware that he is not himself the first to use such a method. Priority, however, is of little moment compared with the excellent result obtained in the case here described. Hands crippled in all sorts of ways and to varying extent by mutilating injuries and burns have offered to the author a wide field of work in which he seems to have displayed high judgment and great patience. The truly heroic treatment recommended for Dupuytren's contracture of the palmar fascia should be noted. Dr. Beck considers that the only satisfactory method of treating an advanced case is by excising the whole of the skin and fascia of the palm and substituting for it an Italian graft from the chest or abdomen. He records a successful case Part II. is, perhaps, of less interest. It will be noticed that, as he himself confesses, Dr. Beck is very fond of the method of Tagliacozzi, and relies largely upon it to provide skin to fill the numerous gaps made by his straightening operations, taking his grafts generally from the chest and less often from the abdomen. We are surprised to find no reference to Volkmann's contracture, which might surely have furnished the author with opportunities to display his skill and resourcefulness.

As a record of actual experience this book will be of the greatest use to surgeons who are engaged in treating such lesions as it describes.

PSYCHOTHERAPY.

Principles of Psychotherapy. By Dr. PIERRE JANET, Member of the Institute, Professor of the Collège de France. Translated by H. M. and E. R. GUTHRIE. London: George Allen and Unwin. 1925. Pp. 322. 10s. 6d.

As a descriptive psychopathologist Janet is unrivalled, though even in his own country the value of his clinical work is not fully recognised, and whilst we are aware of the modern "plague of nerves" we do not profit by his teachings to investigate properly the symptoms of those smitten by the plague. His theory of the dissociation of consciousness provided, both for the manifestations of hysteria and for psychological automatisms, a unifying conception which held the field till the more dynamic theory of the unconscious seemed better to satisfy our craving for explanations in terms of cause and effect. But, though Janet shows the theory of the unconscious to be in the direct line of descent from the observations of Charcot and himself at the Salpêtrière, yet he summarily rejects this later development and places psycho-analysis in the same category as animal magnetism. A third of the book is given to a history of psychotherapies, from the religious treatments like those that made famous the temple of the Asclepieion, through the practices of the animal magnetists to those of the hypnotists, to the methods of Christian Science and the moral suasion of Dubois. Running through all these Janet sees a constant trickle of therapeutic success, but superficial and inexact interpretations have stopped the evolution of processes of treatment that in themselves possessed usefulness and power. Janet's own interpretation of psychopathological disabilities depends upon a postulate of "psychic tension" and the belief that by proper stimulation this tension can be raised or that by economy the "psychic income" can be made sufficient for the needs of life. He notes the importance of "influence" in treatment, and from the practical aspect his methods consist in a thorough understanding of the patient with deliberate guidance and encouragement when the influence is established. As was to be expected, the book is full of shrewd observation, but the reader who comes to it with the hope of learning easy methods of psychotherapy will be discouraged. Janet is cautious as well as experienced, as he shows in writing: "It is not enough for such patients to give them advice or to correct a fault. Patients who have disorders of intelligence, belief, or will, must be made to understand such advice, made to accept it, made to carry it out. This is something very different, and the treatment remains for the most part a problem of psychology."

The book is translated into English which is on the whole easy although there is an occasional obscurity of meaning.

Collected Papers. Vol. III. By SIGM. FREUD, M.D., LL.D. Case Histories. Authorised translation by ALIX and JAMES STRACHEY. London: The Hogarth Press and The Institute of Psycho-Analysis. 1925. Pp. 605. 30s.

THERE are difficulties peculiar to the writing of histories of cases treated by psycho-analysis. The intimacies of the patient's life are so closely concerned that everything leading to identification must be withheld or disguised; no close record can be kept of the analytical findings; links in important chains are so scattered that to join them involves a re-setting of the material; and, finally, the full report of a single analysis would be too voluminous for publication. Pleading these and other difficulties, Freud makes here no attempt to produce conviction in the minds of sceptics, but writes for the information of investigators already convinced by their own experience. The first of the five cases described is one of typical hysteria showing dyspnœa, nervous cough, aphonia, and migraine, with depression and hysterical unsociability, and these commonplace symptoms were bound up with an involved history of emotional events the description of which, with a running commentary, occupies over a hundred pages. The much criticised *Analysis of a Phobia in a five-year-old Boy* follows, with a postscript telling that both phobia and analysis were forgotten by the subject at the age of 19, when the account of his own case came to him as something novel and unknown. To the clinical psychologist the obsessional neuroses are, perhaps, the most interesting of the psycho-neuroses, though their presence is often unrecognised, since the obsessional patient, unlike the hysteric, tends to hide his symptoms from the world in general and his medical adviser in particular. Analyses of two cases are described and, even in their abridged form, they well indicate the complexities of the fantastic logic of the unconscious. More inferential is the application of psycho-analytical principles to elucidate the autobiography of a paranoiac.

The volumes of this series are in historical and logical sequence and should be read in their order of publication. The present one marks a stage at which the general reader can still cope with the difficulties of the subject, though it naturally appeals more to those engaged in treatment.

Problems of Personality. Studies presented to Dr. MORTON PRINCE. By Various Authors. London: The International Library of Psychology, Philosophy, and Scientific Method; Kegan Paul. New York: Harcourt, Brace and Co. 1925. Pp. 434. 18*s*.

Dr. Morton Prince is an American pioneer of psychopathology, best known by his studies of dissociated personality and by his views on the psychogenesis of epilepsy, and a bibliography at the end of this book enables one to trace the development of his interest in general medicine through neurology to the field of psychology and psychopathology. The contributors to this *Festschrift* write with authority in their own spheres, and within the one book the editors have brought together widely divergent views that in this case indicate the growing point of a vigorous branch of knowledge. In the list of writers of the 24 papers the names of Janet, Ernest Jones, Jung, and Putnam mark its international character, and we are reminded that while MacFie Campbell and William McDougall have left this country to take up academic posts at Harvard, the United States has given in exchange John T. MacCurdy to Cambridge University.

Problems of personality involve so many aspects of human behaviour that there is of necessity an absence of continuity of subject. Papers on witchcraft and on medico-legal experiences, on the signatures of Shakespeare, and on the association of psycho-neuroses with mental deficiency, find place under the title of "Abnormal Psychology and Psychopathology," and under the heading of "Unconscious Dynamics and Human Behaviour," Dr. Ely Jelliffe makes an important contribution to the study of unconscious processes in their relation to clinical conditions. Papers by Dr. Knight Dunlap and Dr. H. H. Goddard attack the concept of the unconscious, and Dr. McDougall vigorously criticises Freud's views on social psychology, whilst the psycho-analytical side is represented by MacCurdy and Ernest Jones. It is gratifying to find the psycho-analytical controversy handled upon a scientific plane.

The general reader may find it difficult to estimate the relative values of the views expressed in this book; the psychologically trained reader who feels more confident may bear in mind the warning of MacFie Campbell on page 74: "We are too much accustomed to think that there is only one correct way of dealing with experience, and that the angle, from which we personally come to experience, is the only one from which it can be approached." To both the general and the specialist reader the book can be recommended; it shows that we have travelled far since psychology was described as "the definition of the obvious in terms of the unintelligible."

OPHTHALMOLOGY.

Iris and Ciliary Body. Sémiologie Oculaire. Le Diaphragme Irido-ciliare. By Prof. FELIX TERRIEN, Ophthalmic Surgeon, Beaujon Hospital, Paris. Paris: Masson et Cie. 1924. With 126 illustrations. Pp. 240. Fr.25.

WE have here the second part of a work planned on a generous scale to include not only the symptomatology, but the anatomy, physiology, pathology, and to a partial extent the treatment of the entire eye, details of operative treatment alone being excluded. The first part ("La Calotte Cornéo-scleral") has already been reviewed in these columns,[1] and the remarks then made on the difficulties of considering separately the diseases of the various structures which make up the eye are equally applicable here. Nevertheless, an exhaustive study of the iris and ciliary body, such as this book gives, will be a valuable addition to any ophthalmological library.

In many places the book reflects views current in France and not in this country. Prof. Terrien retains the term rheumatic iritis, which in England has almost gone out of fashion, but he adds that perhaps many cases of rheumatic iritis should be attributed to a latent tuberculosis. In this country we are accustomed to think more of a latent gonorrhœa or of septic infection from the teeth. Tuberculosis of the uveal tract is well illustrated and on the subject of treatment we note that the author almost wholly rejects the use of tuberculin. When we employ tuberculin, he says, in doses so small as certainly to avoid any focal reaction, we deprive that substance of any therapeutic value. On the subject of sympathetic ophthalmia we miss any reference to the characteristic cells infiltrating the choroid described by Fuchs. The author considers favourably the idea that it is a local manifestation of anaphylaxis. In the section on glaucoma, which is included in this volume, the English reader will remark the small place allotted to perimetry as a method of diagnosis, and that in treatment by sclerectomy prominence is given to the method of Lagrange, not to that of Elliot. There are some interesting sections showing retinal atrophy caused by prolonged high tension.

The book is beautifully illustrated, more notable figures being a section of the ora serrata, showing the transition from the functional to the ciliary retina, a syphilitic granuloma at the root of the iris and sections showing the results of an experimental injection of gonococci into the anterior chamber, and demonstrating the beneficial effects of an injection of anti-gonococcal serum.

Medical Ophthalmology. Second edition. By R. FOSTER MOORE, O.B.E., F.R.C.S., Assistant Ophthalmic Surgeon, St. Bartholomew's Hospital; Surgeon, Moorfields Eye Hospital. London: J. and A. Churchill. 1925. With 8 plates and 93 illustrations. Pp. 344. 18*s*.

Mr. Foster Moore's book is considerably expanded since the publication of the first edition in 1922. The whole has been thoroughly revised and there are several new sections. Defect of the visual fields due to lesions of the temporal lobe is a comparatively new subject. There is a diagram showing how the ventral part of the optic radiations plunges first forwards from the external geniculate body into the temporal lobe and then backwards to the calcarine cortex. Intracranial aneurysms causing subarachnoid hæmorrhage are dealt with, and the various ocular symptoms thereby caused, including papillo-œdema and retinal hæmorrhages. Another addition is a section on juvenile and adolescent forms of cerebro-macular degeneration. One of the most interesting additions is a section on the Argyll Robertson pupil from causes other than syphilis. It is based on an original report of the author's on seven cases with Argyll Robertson pupils in whom most careful investigation failed to reveal any evidence of syphilis, or nervous or other disease of any kind. In certain cases it appears to be congenital and a quite isolated phenomenon. According to Kinnier Wilson, it is an occasional occurrence in diffuse toxi-infective states other than neuro-syphilis.

---

[1] THE LANCET, 1923, ii., 334.

As in the first edition, the most interesting and original parts of this work appear to us to be those concerned with retinal arterio-sclerosis and renal and other forms of retinitis. These are especially well illustrated. We know of no other book where the relations between the ophthalmoscopic appearances and microscopic findings in these diseases can be so well studied.

LECTURES ON DISEASES OF CHILDREN.

Fifth edition. By ROBERT HUTCHISON, M.D., F.R.C.P., Physician, London Hospital, and Hospital for Sick Children, Great Ormond-street. London: Edward Arnold. 1925. Pp. 450. 21s.

THE fifth edition of Dr. Hutchison's lectures contains new material which adds considerably to the ground which they cover, while the individuality of the book has been preserved. Minor alterations have been made throughout the text, but the principal additions consist of five new lectures, dealing with acute rheumatic carditis, affections of the liver, the solitary child, abdominal pain, and disorders of growth and development. A new chapter is devoted to convulsions, which no longer appear among the functional disorders. New elements are introduced in the review of the ætiology of rickets. Dr. Hutchison has modified his view of the transmission of syphilis which he now regards as maternal and usually placental. In the treatment of tuberculous peritonitis he favours early surgical measures for all ascitic cases. The new lectures are characterised by the same lucid and homely style as the older ones. The lecture on the problem of the solitary child should be of particular value in directing attention to an aspect of children's disorders which is too commonly neglected.

The popularity of this book among students and practitioners will certainly be maintained by the new edition.

ORGANOTHERAPY.

Opothérapie Clinique; Organothérapie; Formulaire. By MARCEL LAEMMER. Paris: Masson et Cie. 1925. Pp. 151. Fr.10.

Opothérapie Endocrinienne. By GUY LAROCHE. Paris: Masson et Cie. 1925. Pp. 250. Fr.12.

THESE two books, so similar in title and appearance, are very different in content. Dr. Laemmer's book is that of an enthusiast, who is devoted, perhaps on account of some early successes, to treatment by glands and internal secretions, and who applies such treatment for all sorts of diseases. This enthusiasm carries himself and probably many of his patients to believe that material benefit is derived. To any doctor who thinks that bone-marrow, placenta, lung, breast tissue, given by mouth will improve his patient, this book will tell the dosage and method of giving. We cannot, however, avoid a suspicion that the doctor is more at the mercy of the manufacturer than Dr. Laemmer believes.

Dr. Laroche's book, on the other hand, while lacking enthusiasm, brings us in closer touch with modern ideas. It gives in fact a clear exposition of what is now generally believed. After some general remarks, the author gives a useful chapter on the methods of preparation used in making glandular products for medicinal purposes. He then takes each gland in turn, beginning with thyroid medication, and ending with insulin and polyglandular treatment. Each is discussed well and without bias, and the book sums up ably the present position of glandular treatment, or as the French prefer to call it, opotherapy.

DIABETES AND INSULIN.

Insulin. Darstellung, Chemie, Physiologie und Therapeutische Anwendung. Second edition. By Dr. H. STAUB, Privatdozent, 1 Assistent der Med. Klinik in Basel. Berlin: Julius Springer. 1925. Pp. 177.

IT is only a year since the first edition of this book was published and the necessity of a second edition, which is nearly double the size of the first, is a sign of the amount of new work which has been published as a result of the discovery of insulin. Dr. Staub gives a good account of the physiology of the diabetic condition and of the various efforts to discover the internal secretion of the pancreas, some of which only just missed success. The different methods of preparation of insulin are described, and the striking improvements in its manufacture are brought out. The known properties of insulin are enumerated, and the numerous experiments detailed which have helped to elucidate the problems. This part of the book will be valuable to other workers on this subject, since the arguments and experiments are fully discussed and abundant references are given. The clinical section of the book suffers a little by comparison, but mainly because the clinical problems are more difficult. The different methods of treatment are set out together with the ideals to be aimed at, and the indications and contra-indications found in practice. The absence of an index is to be regretted.

Die Insulinbehandlung bei Diabetes Mellitus. By Dr. H. STRAUSS and Dr. M. SIMON. Berlin: S. Karger. 1925. Pp. 74.

THIS is the third edition of a pamphlet which appeared two years ago. It opens with an adequate account of the discovery, properties, and manufacture of insulin, and then goes on to the description of its clinical usage. The authors do not use insulin in mild cases, regarding it as a luxury except in special circumstances. For the moderately and very severe cases they regard it as invaluable, although it has made the dietetic problem much more difficult. An account is given of the Hagedorn and Jensen method for estimation of blood-sugar, which is in many ways the most suitable for hospital work. The account of the theory of insulin action contained in the last 15 pages is too condensed to be clear.

Diabetes Mellitus and its Dietetic Treatment. Thirteenth edition. By B. D. BASU, Major I.M.S. (Ret.) Allahabad: Panini Office. 1925. Pp. 94. Rs.2.

THIS discursive little book contains details of diabetic cures with various carbohydrates. The short account of insulin which, as the preface states, has been embodied in the new edition consists of 15 lines and is hardly adequate. The fasting treatment is dismissed in four pages, and is followed by two pages on the cocoanut cure.

EVOLUTION, HEREDITY, AND VARIATION.

By D. WARD CUTLER, M.A., Chief Protozoologist to the Rothamsted Experimental Station, Harpenden. London: Christophers. 1925. Pp. 147. 4s.

THE importance of modern biology to medicine is not properly appreciated, and the medical implications of the subjects dealt with in this book have hardly begun to be explored. It must surely be as necessary that the ordinary medical student should know about Mendel and the normal curve of variation, as that he should be aware that salt is made up of sodium and chlorine. Medicine consists of individual cases, but medical science badly needs, as Mr. Yule reminded us lately, to think at least in terms of averages, better still in terms of distributions. Mr. Cutler has written quite a good introduction to evolution and heredity, and the publishers have made it available at a really modest price. The historical part in which the evolution of Evolution is traced with interesting personal touches is particularly well done. Thereafter there is rather too much Mendelism and rather too little Galtonism. It may be true that continuous variations arise from a multiplicity of Mendelian factors. On the other hand it may not, and in any case the impossibility of subjecting characters beyond a certain degree of complexity to factorial analysis makes it difficult to be sure about it. There is still plenty of room for looking at the world in Prof. Karl Pearson's way, as well as in Professor Bateson's. But the book will serve as an excellent introduction to the subject, though pathologists will wonder what the author is talking about in the paragraph headed "Blood Tests" (p. 32). If it is meant to be a summary of Nuttall's work on precipitins, it is as strange a travesty as there ever was, and it suggests that, if it would do medical men good to know a little more about Mendel, it might do protozoologists good to know a little more about immunology.

CLINICAL PSYCHOLOGY.

By LOUIS E. BISCH, M.D., Ph.D. London: Baillière, Tindall and Cox; Baltimore: Williams and Wilkins Company. 1925. Pp. 346. 15*s*.

As its name implies, this book deals with methods of mental examination of patients suspected of subnormality or abnormality. The author's scheme of examination is, as is usual with American investigators, elaborate in the extreme, pursuing every possible detail of personal, family, and social history, and including full inquiry into environmental conditions besides the actual personal interview and the use of intelligence and pedagogical tests. It is not suggested that one person should be responsible for all parts of the investigation, but the author is emphatic that the evaluator of the available data should be a medical expert with special training, an opinion which coincides with English practice, although the special training may still be somewhat less complete than is desirable. Most examiners will probably have to be content with a less comprehensive scheme than the book gives. It is fairly certain that much of the information asked for will be unobtainable or inaccurate, and it is also questionable if some of the details inquired into throw much light upon the mentality of the patient.

The rest of the book is essentially a text-book of mental deficiency, but special chapters are included on the epileptic, the syphilitic, and on functional conditions. On the whole the treatment is somewhat superficial: a chapter on the precocious child, which we should be disposed to welcome as a novel feature of such a book, is singularly unilluminating. A useful section distinguishes constitutional psychopathic states, including emotional instability, pathological lying and wandering, from amentia on one hand and insanity on the other. Here again we could have wished for fuller treatment. The author's attitude to the problem of the "moral imbecile" is that of most modern psychologists, who relegate it, rightly or wrongly, to the limbo of forgotten things. Heredity is cursorily dealt with, and it is surprising that, in a book in which Dr. A. F. Tredgold is so frequently quoted, his theories on this subject are completely ignored.

With regard to mental testing, the author advocates the use of certain performance tests, in addition to the Binet-Simon scale, in order to assess intelligence, and is careful to warn his readers that interpretation of tests is even more important than the actual results, a warning that is still necessary. A useful appendix gives complete descriptions of a large number of cases of all types, including some normals and super-normals in intelligence, well worth study by those who are commencing mental testing. The book contains a few good plates, which might have been increased in number, and are not well placed in the book.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

(Continued from p. 248.)

THURSDAY, JULY 23RD.

THE PATHOLOGICAL BASIS OF TREATMENT BY RADIATION.

THE discussion on this subject was opened by Prof. Sidney Russ, who said that the most important therapeutic use of radium and X rays was in the treatment of malignant disease, whilst surgical tuberculosis and the deficiency diseases were those most susceptible to light and ultra-violet therapy. In the laying down of the pathological foundations of such therapy it was necessary not only to specify the cellular changes resulting from irradiation, but also to correlate them with the dosage employed and to indicate the processes by which the changes are brought about. The degree to which visible and ultra-violet radiation penetrated the tissues was small; it became, in fact, gradually smaller and smaller as pigmentation due to this exposure increased, and there was a natural tendency to attribute the reactions which occurred to some effect set up either in the blood-stream or the lymph, or to suppose that the nervous system played some important though obscure part. The pathological basis of heliotherapy was not so well defined as that of treatment by X rays and radium. Pathological researches had shown that cellular degeneration was a frequent sequel to irradiation of tissues. These changes might be due either to a direct action of the radiation upon the internal constituents of the cell, or to a direct action of the radiation upon the interfaces of the cell, or to an indirect action which irradiation initiated. Prof. Russ said that he would like to hear these alternatives discussed—his own views inclining him to the opinion that some interfacial action plays the dominant part in the first instance. Considering the tissues as systems involving a continuous adjustment of their equilibrium, he thought that the upset of such equilibria was more likely to have a profound effect upon the composite mass than the actual breaking down of the chemical complexes within the cell. In tissue clearly damaged by radiation we had evidence of the whole equilibrium being upset. In tissue submitted to doses which had no visible effect whatever we had the equilibrium entirely conserved, as it was towards visible radiation, and in those cases where only slight visible effects were produced; yet with integrity of the structure we might perhaps look upon them as stable yet entirely new conditions of equilibrium. Various tissues responded differently to a dose of radiation according to whether the time of exposure was short, the quantity being large; or long, the quantity being small. It was still obscure why there should be a difference in the reaction of the tissues when the actual dose was constant, the only variation being in the conditions of exposure. The effects of radiation on the tissues were unique. In living tissues we were confronted with a complex continuously adjusting its equilibrium with contiguous or enveloping structures, and experimental methods would appear more likely to reach success if the complex were kept in mind without the effort of reducing it to simple terms.

Dr. T. S. P. Strangeways gave a description of the effect of irradiation by X rays on cells undergoing division in tissue cultures of the embryonic fowl and on the embryo while in the unopened shell. The effects were observed during experiments which are being carried on by himself and his co-workers, Dr. R. G. Canti, Dr. M. Donaldson, Prof. Hopwood, and Dr. F. G. Spear. These experiments indicated that even small doses had a pronounced inhibitory effect on cell division and that they prevented new cells from coming into mitosis. Such small doses caused a definite retardation of the different phases of mitosis in those cells which had already begun to divide before the commencement of irradiation. It was found that there was no definite evidence that cells in actual mitosis were more vulnerable than those in a vegetative state. It was further found that, within the limits of the experiments, variation in the quality of the incident dose of X rays as measured by a Friedrich iontoquantimeter had no appreciable influence on the dose required to prevent mitosis.

Miss E. M. Hume read a paper on the

Action of Ultra-violet Light upon the Growth of Rats,

in which she described experimental work which proved that light cannot substitute cod-liver oil indefinitely for the growth and well-being of the rat. Although calcification may be promoted by the light, yet the set of symptoms due to injury to the mucous membrane eventually display themselves and lead to a fatal issue. It appears that some reserve is gradually exhausted. Possibly this other limiting factor is the original vitamin A, though how far this is completely independent of the light or antirachitic factor cannot at present be determined. The nature of the antirachitic vitamin or of any inactive precursor substance is at present uncertain; it appears to be fat-soluble; but it is not even proved that there is one specific substance. Antirachitic properties have been conferred upon various inactive substances by exposing them to ultra-violet radiation, and when fed to rats they produce the same effect as does direct irradiation.

Dr. A. Piney spoke on changes in the blood and blood-forming organs following exposure to X rays. On the bone marrow the effects are essentially destructive in character, and are seen in the shape of nuclear degeneration of the essential cells, although there is no change in the adipose tissue. In the lymphatic glands the results of radiation resemble those due to inanition, but occur much more rapidly. The involution of the thymus resulting from X rays is rapid and extreme. The changes in the spleen are more difficult to interpret because considerable variations occur in response to different doses. Ziegler was able to show that, if the dosage were so adjusted as to injure the Malpighian bodies without damage to the pulp, it was possible to demonstrate the occurrence of myeloid metaplasia in the latter structure within a few days. In the blood the great majority of investigators have shown that there is a distinct reduction in the number of leucocytes, which depends mainly upon decrease of the neutrophiles with consequent relative lymphocytosis. The basis of the changes occurring in the blood is still a matter of controversy.

Dr. R. G. Canti and Dr. F. G. Spear discussed the

Biological Action of Gamma Ray Irradiation on Tissue Cultures.

The experiments were undertaken as a result of certain observations on the effects of radium irradiation on cases of carcinoma of the *cervix* treated by Dr. Malcolm Donaldson. Most striking among these observations was the *absence of mitosis* which was observed as soon as the radium was removed after 24 hours *in situ*. The preliminary observations on tissue cultures were purely qualitative. Living cells were examined in the thermostat for prolonged periods under the microscope whilst under the influence of radium. The following conclusions had been reached: (1) Cells in mitosis divided in what appeared to be normal fashion and the daughter cells developed into full-sized apparently normal vegetative cells and did not again go into mitosis. (2) For a certain period, the length of which depended on the intensity of irradiation, cells continued to come into mitosis as before irradiation, but at the end of this period no more cells came into mitosis.

After satisfying themselves that radium irradiation brought about very definite changes in the cultures, they had undertaken quantitative experiments with a view to determining whether the same amount of irradiated energy brought about the same biological effects irrespective of the time over which that energy was radiated—i.e., if the radium were moved further from the tissue culture to a distance whereby the incident intensity were halved, then would double the time be required to produce the same biological effect? The physical measurements of intensity of radiation at various distances were made by a photographic method, and curves were drawn up comparing the physical effects with the biological effects as determined by the time taken at various distances to cause cessation of mitosis. These curves showed that when the radium was near the tissue culture there was no observed departure from the physical readings, but that at a greater distance a longer time was required to bring about the same effect than would be anticipated from purely physical laws. Further, the shape of the biological curve suggested that beyond a certain critical distance from the radium no biological effect might be expected. It was pointed out that, at this stage of the investigation, this course of events could not necessarily be translated into conditions when radium is applied to carcinoma *in vivo*.

A paper was read by Dr. Helen Mackay on

Foodstuffs Irradiated with Ultra-violet Light

and their effect on the bone lesions of rachitic children. Dr. H. F. Shaw had collaborated in this work, and he showed a number of lantern slides of X ray photographs. Their experimental work led them to the conclusion that the effect of direct exposure to ultra-violet light on the bone lesions of a rachitic patient appear to be dependent upon the power of light to produce in certain substances the so-called antirachitic factor. Rapid healing of the bone lesions in children can be brought about by dried milk irradiated with ultra-violet light from the mercury arc, and this antirachitic potency of the milk withstands ten minutes' boiling. Three ounces daily of white flour similarly irradiated had little or no effect, and the antirachitic power of 6 drachms daily of irradiated cotton-seed oil is probably slight. There is reason to believe that a prolonged exposure to ultra-violet light will destroy the antirachitic potency a shorter exposure has imparted. It seems probable that the action of a foodstuff artificially rendered antirachitic by irradiation with ultra-violet light is identical with the action of a naturally occurring foodstuff containing the antirachitic factor, and that no more beneficial effect is to be expected from irradiating a patient's milk than from giving cod-liver oil. But when cod-liver oil cannot satisfactorily be given then irradiated substance may in the future prove of considerable value.

At the conclusion of this communication an opportunity was given for questions to be addressed to the readers of papers, and the following took part in the subsequent discussion: Dr. J. Barcroft Anderson Dr. Braxton Hicks, and Prof. J. C. G. Ledingham.

FRIDAY, JULY 24TH.

THE PRESENT POSITION OF PATHOLOGY AND BACTERIOLOGY IN THIS COUNTRY WITH SPECIAL REFERENCE TO RESEARCH.

In opening a discussion on this subject the President of the Section, Prof. J. C. G. Ledingham, remarked that in the last annual report of the Medical Research Council the parts played respectively by physiology, pathology, bacteriology, biochemistry, and experimental medicine in contributing to the general advance of practical medicine in this country were discussed at considerable length. The report recorded praiseworthy progress in the fields of physiology, but found little to place to the credit of pathology and bacteriology during the last five years. This apparent sterility was attributed to the stated fact that the purely utilitarian side of pathology and bacteriology has lessened the opportunities of their exponents for contributing to the advance of new knowledge, and in some cases tended to withdraw from active research life workers who might otherwise have added to knowledge. Those universities were criticised which maintain the departments of pathology and bacteriology from fees received for the routine performance of diagnosis tests made on behalf of outside bodies. Prof. Ledingham agreed with the report of the M.R.C. that these practices are liable to grave abuse, and that immediate reform is necessary in the best interests of pathology, but declared that the place which routine diagnosis takes in the training of the professional bacteriologist cannot be ignored. Routine diagnosis is an excellent training for research; but when the research stage is reached routine diagnosis should not be allowed to interfere with the new interests. The best pathological service can be realised only when ward and laboratory and patient or laboratory are brought as near as possible, and mutual consultation on equal footing can be arranged. The inspiration to research need not of necessity be subdued in the atmosphere of routine work; but the research output might be very considerably increased if the training of men for professional routine pathology and bacteriology were more carefully organised. Bacteriology must be recognised as a broad and fundamental branch of science, coördinate with, rather than subordinate to, the other great divisions of biology. Therefore the universities should train the graduate aspiring to become a professional bacteriologist by providing advanced instruction in general bacteriology. Though posts for bacteriologists have increased of recent years there appears to have been no corresponding increase in the field of suitable candidates. There are welcome signs that increased facilities for training pathology laboratory workers may soon be available. Prof. Ledingham passed on to consider the research institutes, which occupy a somewhat different, but not essentially different, position from that of the universities. Since all the ancillary sciences which minister to medicine are usually represented in the institute, the staff forms a self-contained unit. Experience has shown that pathology and bacteriology, research in serum-therapy and specific disease prevention, supply a constant stream of problems which may or may not have their immediate echo in practical medicine. Occasions arise, however, when the direct appeal to the human patient becomes insistent; and both the Pasteur and Rockefeller institutes have made provision for this by the establishment of research hospitals. At the Lister Institute, Prof. Ledingham remarked, a site is ready for a research hospital when the necessary funds can be obtained.

In spite of the handicaps under which these sciences labour in this country at present, how far is the criticism expressed in the M.R.C.'s report justified? Prof. Ledingham considered that the author of the M.R.C.'s report was unwise in attempting an estimate of the achievements over a short period of pathology and bacteriology as compared with those of physiology and biochemistry. He declared that some of the arguments advanced to support the points were founded on irrelevant or inaccurate statements, and he concluded an eloquent appeal for a less materialistic attitude with these words: "If bacteriology fails in five years to throw up an attractive flower, heaven knows that in the past 40 years it has thrown up many. Let it rest for a while in the apparent slumber of growth and rejuvenescence, working out anew its fundamental problems in activities which do not attract perchance the attention of the superficial observer."

Prof. M. J. Stewart (Leeds) said that he found himself fully in sympathy with Prof. Ledingham's point of view. He spoke in particular of the training of young pathologists, observing that this required the abundant supply of pathological material for their instruction. There was usually little difficulty in imparting to a promising laboratory worker sufficient skill to carry out routine work; but often he lacked that broad fundamental training in mathematics, physics, and chemistry which would enable him to tackle with success the great problems of disease still awaiting solution. But facilities for better training were increasing. Thus the University of Leeds offers a four years' course leading to the degree of bachelor of science with honours in bacteriology. Within recent years there had been a revival of interest in morbid anatomy, and the prophecies of its decline had not been fulfilled. He thought that the study of morbid anatomy would be advanced if the teacher of histology approached the subject from the pathological point of view. Turning to the criticisms expressed in the last annual report of the Medical Research Council, he said he did not agree, among other points, with the wholesale ban on routine work therein pronounced. He pointed to an inconsistent attitude on the part of the author of the M.R.C.'s report to pathology and physiology. He concluded by entering a plea for a much maligned side of the pathologist's work—namely, "dead-room pathology"—and declared that the post-mortem room still provided an invaluable and almost inexhaustible field for original research.

Prof. Carl Browning (Glasgow) spoke particularly of the training of research workers, the facilities for research, and the endowment of research. After medical training he thought it to be of the greatest advantage to the pathologist to hold for several years a whole-time research fellowship. On the subject of facilities for research he considered it to be not excessive if every member of the staff of every pathological department had at least half of his working time free to devote to research work. He deplored the neglect of the facilities which exist at fever hospitals for the study of infectious disease, and appealed for a closer association of research in animal and human pathology.

Speaking of the endowment of research, he agreed that the M.R.C. had given almost inestimable assistance by paying both for personnel and material, but considered that endowments should be provided without the fettering condition of this being applied solely to the investigation of some particular specified problem or disease.

Dr. Braxton Hicks, Dr. J. A. Arkwright, Dr. C. C. Okell, and Dr. C. E. Dukes contributed to the discussion. In summing up, Prof. Ledingham said that he hoped that steps would be taken to bring the unanimous conclusions of the pathological section of the B.M.A. to the notice of all universities and hospitals of the country.

EXHIBITION OF INSTRUMENTS, DRUGS, FOODS, AND APPLIANCES.

SURGICAL INSTRUMENTS AND APPLIANCES.

THIS year sees the addition of much interesting surgical apparatus to the range shown in 1924.—[46] Allen and Hanburys, Ltd. (Bethnal Green, London, E.C. 2), showed various improvements in the St. Bartholomew's Hospital pattern operation table of last year, and a new horizontal model high-pressure steriliser, in addition to a wide range of instruments for general and special surgery.—[38] Arnold and Sons (John Bell and Croyden, Ltd., 50, Wigmore-street, London, W. 1): a new operation table fitted on double cylinder oil pump base and improved movement for raising and lowering the head and leg pieces, and a selection of surgeon's instruments made entirely of Firth's stainless silver steel. Their "Electrophonoide," an apparatus for re-educating the sense of hearing, was also being demonstrated.—[50] Down Bros., Ltd. (21, St. Thomas's-street, London, S.E. 1) showed a collection of surgical instruments and appliances.—[44] The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, London, E.C. 1) had a large collection of hospital furniture and instruments, including a new pedestal operation table, Cumberbatch and Robinson's diathermy electrodes, and the "Jupiter" sun lamp.—[43] Mayer and Phelps (59, New Cavendish-street, London, W. 1): a selection of instruments and appliances, particularly the "Reavell-Moseley" electric rotary pump, for pressure and suction, which can be used to administer anæsthetic vapours, to work sprays, evacuate cysts, or to remove blood and secretions from an operation area, thus saving much time in swabbing; also a complete set of instruments for per-oral endoscopy by Irwin Moore, so arranged that the tubes can be used for either proximal or terminal illumination; an artificial larynx by Tapier, and a selection of tubes for use after total laryngectomy; Hammond's combined urological syringe for local anæsthesia or hypodermic, intramuscular, or intravenous injection, for lumbar puncture, and for injecting the anterior and posterior urethra and the pelvis of the kidney; also the "Chiron" ring pessaries.—[40] John Weiss and Son, Ltd. (287, Oxford-street, London, W. 1): a complete display of general surgical instruments, including the Vaquez-Laubry sphygmotensiophone; Ryall's cysto-urethroscope and combined cystoscopic lithotrite; Sinclair's *intracapsular forceps and outfit*, and a projection and operation lamp suitable for any voltage, with water-filter attachment for demonstrating microscopic slides.—[41] Hoskins and Sewell, Ltd. (Bordesley, Birmingham): an obstetric bed designed by *Dr. Remington Hobbs* for drainage treatment. This is made in separate halves, each having four legs and wheels; the foot end can be pulled away and stirrups put in the other half, minimising disturbance of the patient; a number of patent wheeling bedsteads particularly adapted to the open-air treatment of tuberculosis; the Alton sunshade for the head and shoulders of a patient receiving sun treatment.

Among the special instruments:—[2] G. H. Zeal, *Ltd.* (75, St. John-street, London, E.C. 1): the "Repello" clinical thermometer, which is reset by pressing a top bulb and requires no shaking. The "*Acello re-setting*" *clinical thermometer case*, for those who find it difficult to shake the ordinary thermometer; and an aseptic thermometer with graduations on the glass outer case and an unmarked stem, which is unharmed by any antiseptic solution.—[12] Theodore Hamblin, *Ltd.* (15, Wigmore-street, London, W. 1): a collection of ophthalmic instruments and equipment, including the new Lister hand-projection lamp for operating; a new luminous *Morton ophthalmoscope* for use with direct and indirect methods; *a new astigmatic test* with grey background and an improved form of the Lister perimeter and scotometer. They had also on view a series of drawings and lantern slides of eye conditions, *made* by their staff of trained draughtsmen.—[18] The Genito-Urinary *Manufacturing* Co., Ltd. (64, Great Portland-street, London, W. 1): a selection of all the latest instruments of bladder and kidney surgery, and particularly a series of diagnostic *instruments* not previously manufactured in this country.—[20] The British Hanovia Quartz *Lamp* Co., Ltd. (Slough): their quartz mercury anode type lamps, for direct current and alternating current without rectification.—[30] The Dowsing Radiant Heat Co., Ltd. (91, Baker-street, London, W. 1), showed an improved pattern of the Sunrae carbon arc lamp for ultra-violet radiation; an improved bed and lighter local appliances, and a bed-warmer fed from the house supply.—[31] Rayner and Keeler, Ltd. (Kemp Town, Brighton): various operating lamps and ophthalmoscopes, particularly a triple-beam operating lamp minimising shadow, an adjustable ophthalmic *bracket* fixed above the patient's head, and a slit-lamp with single focus for microscope and lamp; also Dr. R. Wallace Henry's new light perception instrument which was *demonstrated* at the Sectional Meeting.—[33] Hague and Son (32, Broad-street, Bath): *oph*thalmic instruments, including the Zeiss simplified Gullstrand ophthalmoscope and the Zeiss parallax refractometer, embodying slit-lamp and ophthalmoscope.—[45] The Inhaling *Drug* and Apparatus Co. (30, Grosvenor-place, London, S.W. 1): the *Apnea* inhaling apparatus (Spiess Drager), which transforms any liquid into an infinitely *fine* vapour for inhalation. Drugs, including insulin, may be administered through the respiratory organs by this means, reaching the circulation more rapidly than by hypodermic injection.—[52] H. E. Curtis and Son, Ltd. (7, *Mandeville-place, London*, W. 1): a series of abdominal supports and colostomy trusses, and a medicinal liquid paraffin "Colonol."—[62] General Acoustics, Ltd. (77, *Wigmore-street, London*, W. 1): the latest aids for the deaf, electrical and non-electrical, including a new microphone encased in light imitation tortoise-shell, giving a mellower sound; and a special theatre-box that enables the *deaf to hear loud speakers* as well as plays, speeches, and sermons.—[80] Ardente-Acoustique (95, Wigmore-street, London, W. 1): the new 1925 types, a distinct advancement on previous models with complete freedom from metallic or extraneous sounds.—[69] *Pedestros*, Ltd. (10, Conduit-street, London, W. 1): "Desoutter" light metal artificial legs for all types of amputation.—[84] B. Smith (6, Cambridge-*terrace, Widcombe Hill, Bath*): a series of adjustable aluminium limbs, splints, and callipers for bone-grafting, &c., with special apparatus for rapid lengthening and shortening; *also a showcase of* photographs of wounded men fitted with artificial limbs and appliances at the Bath War and Ministry of Pensions Hospital, 1915–22.

Other firms supplying surgical dressings:—[7] Antiphlogistine (Denver Chemical Manufacturing Co., London, E.C. 3) and [5] The Thermogene Co., *Ltd.* (Haywards Heath, Sussex) were demonstrating their well-known products.—[4] Fassett and Johnson, Ltd., were showing a full range of Seabury and *Johnson plasters*, dressings, and surgical requisites, including Mead's rubber adhesive plaster and the "Gold Cross" absorbent cotton.—[16] Jeyes' Sanitary Compounds Co., Ltd. (64, *Cannon-street*, London, E.C. 3): various preparations of cyllin, an antiseptic which has a Rideal-Walker coefficient for *B. typhosus*, 24–26.—[37] The Jaeger Co., Ltd. (95, Milton-street, London, E.C. 2): a selection of underwear and outerwear for men, women and *children*; *also* the "Domen" belts for pregnancy, hernia, and floating kidneys.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

[46] Allen and Hanburys (37, Lombard-street, London, E.C. 3): in addition to the well-known "Byno" and "Polyglandin" *preparations*, the "A. B" brand of insulin, "Osmo" Kaolin, a specially purified *colloidal* kaolin, *prepared* by electro-osmosis and used in the treatment of intestinal toxæmias; "Sea-cones," suppositories containing chloral hydrate and bromide, for sea-sickness; "*Iodolysin*," a soluble compound of thiosinamin, containing 47 per *cent. of* iodine; a diabetic flour; and surgical Pitibulin, double the strength of the obstetrical Pitibulin, for surgical shock. "Antivirus" is a series of specific local immunisers *prepared* from the broth culture in which bacteria have been grown.—[47] *Boots Pure Drug Co.*, Ltd. (Station-street, Nottingham): a representative display of the firm's *special* medical products, fine chemicals, medicated capsules, and compressed tablets; *gonococcal* vaccines made at St. Thomas's Hospital; capsules of hexyl resorcinol, a new intestinal antiseptic, and a full range of the antivenereal preparations "Stabilarsan," "Bismostab," "Thiostab," "Acriflavine," and "Chloramine-T." The "Alpine" *sun* lamp was demonstrated in the local branch.—[83] C. J. Hewlett and Son, Ltd. (35–42, Charlotte-street, and 83–85, Curtain-road, London, E.C. 3): a number of *original* preparations, including Mist. Pepsinæ Co. c. Bismutho; Mist. Hepatica Conc.; an antiseptic cream; "Somnigen," a preparation of opium free from disagreeable *odour*, taste, and after-effects; "Veronigen," a liquid preparation of barbitone; "*Hormonigen*," a compressed pluriglandular tablet, and Dr. Crofton's human tubercle bacillus *solution*.—[64] The Hoffmann-La Roche Chemical Works, Ltd. (7, 8, Idol-lane, *London, E.C. 3*): besides the well-known "Omnopon," "Sedobrol," and "Spasmalgin," "Allonal" a non-narcotic analgesic; chocolate iodostearin tablets used in the prophylaxis and treatment of simple goitre in school-children, and "Digalen" amorphous digitoxin, a chemically standardised and physio-

logically controlled preparation of digitalis, free from inactive and toxic constituents.—[78, 79] Oppenheimer, Son and Co., Ltd. (179, Queen Victoria-street, London, E.C. 4): in addition to the various palatinoids, bipalatinoids and "Roboleine"; an aeriser for reducing all liquids to a fine invisible smoke for the treatment of affections of the respiratory tract; "Balmosa," an analgesic antiseptic cream; and "Pinheroin," containing terpene hydrate and heroin hydrochlor. with essence of Canadian pine.—[11] Parke, Davis and Co. (50, Beak-street, London, W. 1): a series of pharmaceutical preparations, including "Dibromin," a crystalline germicide containing about 56 per cent. of bromine; "Metagen," a concentrated vitamin preparation and "Metagen" combined with cod-liver oil; a 1 per cent. solution of silver nitrate in wax capsules to instil into the eye of the new-born baby; and a selection from the series of vaccines prepared at St. Mary's Hospital.—[51] Burroughs Wellcome and Co., Ltd. (Snow Hill Buildings, London, E.C. 1): amongst additions to the list of "Tabloid" products: "Tabloid" digitalis leaf, presenting the whole substance and activity of selected digitalis leaves; "Tabloid" hexamine and "Tabloid" methylene, blue; "Kharsulphan," a new antisyphilitic for hypodermic or intramuscular injection; "Hypoloid" bismuth metal suspended in isotonic glucose solution; a demonstration of the stages in preparation of "Tabloid" thyroid gland and "Wellcome" insulin; "Tabloid" iodicin, gr. 3, for adults and with chocolate base for children; and a series of vaccines and sera.—[67] Burgoyne, Burbidges and Co., Ltd. (East Ham, London, E. 6): a collection of pharmaceutical preparations, including Cooper's colloids; "Chlorobrome" for insomnia and sea-sickness; "Neutramyne" tablets of cod-liver oil, and ethyl chaulmoograte sodium morrhuate for leprosy.—[68] Ferris and Co., Ltd. (Bristol): pharmaceutical specialties, including Elixir parathyroid and calcium lactate; Elixir "Vi-glandin," a preparation of thyroid, pituitary, orchitic and ovarian substance in combination with the glycerophosphates of calcium, iron, sodium, potassium, and magnesium; "Otoids"; "Sterisols," for hypodermic injection; surgical instruments and dressings and scientific apparatus.—[77] Lionel Cooper (14, Henrietta-street, London, W.C. 2): various drugs, including "Milesia," a soluble tablet containing gr. 3 magnesium hydrate, plain or flavoured with peppermint; "Presoiod," an iodine solution prepared from the formula of Prof. Pregl, plain, concentrated or pepsinated; "Salvitæ," a uric acid solvent in granular form; and "Sil-Al," a physiologically pure silicate of aluminium in the form of a white tasteless powder which forms a colloidal suspension when mixed with water.

Special pharmaceutical preparations were shown by [6] J. C. Eno, Ltd. (Victoria Embankment, London, E.C. 4): the well-known effervescent saline laxative.—[8] Crookes' Collosols (The Crookes Laboratories, 22, Chenies-street, London, W.C. 1): the wide range of "Collosol" drugs, among the latest additions being "Collosol Lactalumina," an antacid; "Collosol Ichthyol," a British preparation; "Collosol Kaolin"; also a "Collosol Kataplasma Iodokaolin" for use as a poultice in inflammatory conditions.—[26] W. Dederich, Ltd. (Stanley House, Dean Stanley-street, London, S.W. 1): the original "Ichthyol" sulphonated schist oil preparation; "Pantosept" tablets, which when dissolved in water produce a solution of hypochlorous acid for antiseptic purposes. This firm is also the agent for the preparations of J. D. Riedel, A.G., Berlin, whose "Noctal," a soporific without disagreeable after-effects, deserves mention.—[36] The Semprolin Co., Ltd. (18, Leather-lane, London, E.C. 1): the various combinations of "Semprolin" emulsion of paraffin oil; the plain oil which may be prescribed with anything the practitioner desires; the emulsion with phenolphthalein; with guaiacol carbonate; with salol; and with bismuth and pepsin. Also "Carmex," the mild laxative and corrective for children.—[49] Armour and Co. (Queen's House, Kingsway, London, W.C. 2): a series of endocrine preparations in tablet, capsule, powder, hypodermic, and liquid form. The ovarian and corpus luteum preparations are now standardised as well as the pituitary.—[54] Genatosan, Ltd. (Loughborough, Leicestershire): in addition to their well-known "Sanatogen," "Formamint," "Genasprin," and detoxicated vaccines; "Nasmint," a germicidal snuff; and a particularly pure and stable calf lymph.—[57] A. and M. Zimmermann, Ltd. (3, Lloyd's-avenue, London, E.C. 3): several specialties from the Schering laboratories, including the hypnotic "Medinal"; "Atophan"; "Atophanyl," a solution of the sodium salts of "Atophan" and aspirin with novocaine; "Arcanol," a combination of "Atophan" and aspirin used for influenza; "Veramon," a powerful non-habit-forming analgesic.—[63] Deshell Laboratories, Ltd. (150, Southampton-row, London, W.C. 1): "Petrolagar," a compound of agar-agar with paraffin oil in its four forms: plain, with phenolphthalein, without sugar for diabetic cases, and with alkali for hyperacidity and the constipation of pregnancy.—[72] The Anglo-American Oil Co., Ltd. (Albert-street, London, N.W. 1): the well-known "Nujol" liquid paraffin; and "Mistol," a combination of menthol, camphor, and eucalyptol with paraffin; also "Cream of Nujol with Agar," and a new insecticide spray "Flit."—[80] J. W. Carnrick and Co. (40, Lexington-street, London, W. 1): various pluriglandular formulæ, including the well-known "Hormotone" and "Trypsogen"; also "Erythrogen," a bone-marrow preparation for anæmia; and "Rhythmin," a peristaltic stimulant.—[15] The British Dye-Stuffs Corporation, Ltd. (70, Spring-gardens, Manchester): the drugs S.U.M. 36 and S.U.P. 36; the arseno-benzine preparations for intravenous or intramuscular injection in gonorrhœa and inflammatory conditions.

Among toilet preparations:—[48] "Pepsodent," the pioneer acid dentifrice, and [56] Kolynos Inc. (Chenies-street, London, W.C. 1) demonstrated their dental creams.

Food Products.

[18] Brooks and Warburton, Ltd. [40–42, Lexington-street, London, W. 1): the various Mead's infant diet materials, including "Dextri-Maltose," for use in all cases where sugar is needed; "Re-Co-Lac," a reconstructed milk powder; and certified Newfoundland cod-liver oil, a biologically tested and standardised preparation.—[23] Thew, Hooker and Gilbey, Ltd. (Buckingham): Hooker's Malted Milk, and "Lacta," an evaporated milk for infant feeding.—[34] Benger's Food, Ltd. (Manchester): the various products of the company, including peptonising powders, peptonised beef, and chicken jellies and lentil flour; illustrated by photographic slides showing the action of an artificial gastric juice on milk and milk mixtures.—[35] Montgomerie and Co., Ltd. (Ibrox, Glasgow), the proprietors of Bermaline bread: two new brands of infant and invalid food, "Berina" food for children up to 6 months, and "Berina" Malted Milk for older patients.—[39] Trufood, Ltd. (Lever House, Blackfriars, E.C. 4): "Trufood Full Cream Milk," a full cream Cheshire dairy milk in powder form; "Seeway," whey in powdered form for delicate and premature infants; and "Humanised Trufood," which essentially agrees in its composition with breast milk.—[59] Virol, Ltd. (Hanger-lane, Ealing, London, W. 5): the well-known "Virol," a composition of marrow-fat, glycerine extract of red bone-marrow, malt extract, eggs, lemon syrup and salts of lime and iron; "Virolax," an emulsion of Virol with 60 per cent. liquid paraffin; and "Virol and Milk," a tonic food for invalids, nursing mothers, and athletes.—[61] Cadbury Bros., Ltd. (Bournville): cocoa and chocolate.—[66] Ambrosia, Ltd. (Huntley and Palmer, Ltd., Reading): "Ambrosia Devonshire Milk" for infants and invalids; "Ambrosia Cocoa and Milk," a nutritious food for growing children and nursing mothers.—[70] Glaxo, Ltd. (56, Osna-

burgh-street, London, N.W. 1): in addition to "Glaxo" full cream, three-quarter cream, half cream, and malted food, "Prescription Glaxo," a dried milk powder giving percentages closely approximating to breast milk; "Glax-Ovo," a combination of milk, malt, and cocoa with ostelin; and "Ostelin," a high concentration of the antirachitic unsaponifiable fraction of cod-liver oil, three drops being equivalent to 1 drachm of the original oil.—[81] Oxo, Ltd. (Thames House, Queen-street-place, London, E.C. 4): besides "Oxo," the peptonised and unseasoned hospital "Oxo"; Lemco unseasoned beef extract; the various "Oxoid" endocrine preparations in tablet and food extract forms, of which the latest is "Pitoxylin," a sterile and protein-free solution of the purified oxytocic and pressor substances from the posterior lobe of the pituitary, supplied in a 10 per cent. obstetrical and general extract and a 20 per cent. surgical extract.

MEDICINAL AND MINERAL WATERS AND SPAS.

[20] Ingram and Royle, Ltd. (45, Belvedere-road, London, S.E. 1): the bottled Vichy-Célestins, Contrexeville, and Hunyadi János waters.—[17] Harrogate: This spa is particularly active in scientific work. All the continental methods of treatment are available in addition to several original methods. An entirely new apparatus has been installed in the throat and nose department and many long-standing nasal troubles have yielded to the administration of the waters in an atomised condition. A special bathroom has been equipped with laboratory and clinical apparatus, and is used solely for balneological research. A permanent scientific officer and analyst has been appointed, and the attendants are fully certificated.—[65] Buxton: Attractive booklets, setting out the value of radio-active thermal water at 82° F. and the chalybeate spring. The baths contain swimming pools and immersion baths, in all of which the water is continually running from the springs. The attendants are specially trained and examined by medical men for their certificate.—[60] Droitwich, which is developing its technical work and considering the establishment of an electro-medical section. The brine content of the waters is considerably higher than that of any other European mineral springs. The social amenities are very complete, and include tennis and croquet lawns and a golf course, photographs of which were on view.—[42] Gaymer's Cider (Attleborough, Norfolk) were demonstrating for their twenty-eighth consecutive year an assortment of their various brands, of which their dry ciders have gained widespread medical approval.—[10] Alexander Riddle and Co., Ltd. (Bancroft-road, London): Stoewer's lime-juice and lemon-juice preparations, made from selected fruit and refined sugar, without artificial colouring, essence or acid, containing vitamin C.

MICROSCOPES AND SCIENTIFIC APPARATUS.

[3] The Tintometer, Limited (The Colour Laboratories, Salisbury): a variety of pathological apparatus, particularly the "Red Cell Suspensionometer" of Dr. H. St. Amand Agate for the Wassermann test; and an improved form of Oliver's hæmoglobinometer.—[15] The British Dye-Stuffs Corporation, Ltd. (Manchester): a range of indicators for pH values; microscopic stains, specially tested pathologically and chemically; and chemical reagents.—[24] O. Sichel and Co., Ltd. (52, Bunhill-row, London, E.C. 1): the "Kinograph," an apparatus suitable for photographing living subjects and pathological specimens—it will do every photographic process, including enlarging and reducing from X ray negatives, and the very high-powered and steady illumination employed gives perfect control over exposures; also the "Eco-Dry" cabinet, heated by electricity, for the rapid drying of X ray and other negatives.—[28] British Drug Houses, Ltd. (16–30, Graham-street, London, N. 1): the "B.D.H. Capillator," a series of sealed capillary tubes filled with buffer solutions containing indicator, which give very accurate pH indications with the use of a minimum of fluid; the "B.D.H. Comparator" case for storing sealed buffer tubes; the "B.D.H. Universal Indicator," showing the whole range of spectrum colours over a wide pH range; and the "B.D.H." histologically standardised microscopic stains.—[32] Messrs. Chas. Hearson and Co., Ltd. (68, Willow-walk, London, S.E. 1): several models of the well-known Reichert microscopes, for which they are sole agents; a spectroscopic eye-piece by Reichert; the dark ground illuminator of Prof. Arzt; a high-speed centrifuge giving 3000–10,000 revolutions per minute, suitable for the separation of ultra-microscopic viruses; and "Cornic's Half-Shadow Saccharimeter" for estimating grape-sugar and albumin in urine.—[53] Short and Mason, Ltd. (Atlantic House, 45–50, Holborn Viaduct, London, E.C. 1): the "Tycos" sphygmomanometers, portable and surgery types; also clinical and recording thermometers; and the "Micro-Barograph," a very sensitive recording barometer.—[76] Baird and Tatlock, Ltd. (14–15, Cross-street, Hatton-garden, London, E.C. 1): a series of autoclaves, centrifuges and other bacteriological apparatus; fittings of all kinds for hospital and public health laboratories; and apparatus for blood-sugar estimation.—[14] Eastman (Kingsway, London, W.C. 1): a series of "Dupli-Tized" X ray film negatives, with reductions and enlargements, showing the legibility and uniformity of the image; apparatus for simplified methods of development.

MEDICAL AGENCIES.

[9] The Medical Insurance Agency (420, Strand, London, W.C. 2), in addition to their usual literature, had a typical doctor's car for demonstration, supplied by Mann, Egerton and Co., and a qualified engineer to advise on car questions.—[73] The Medical Sickness, Annuity and Life Assurance Society, Ltd. (300, High Holborn, W.C. 1): demonstrations of various policies, including their "Every Contingency" Sickness, Accident and Endowment Policy; and the "Perfect" Educational Assurance policy.—[88] Arnold and Sons (50–52, Wigmore-street, London, W. 1): a medical transfer department for practices and locum-tenents.

BOOKS.

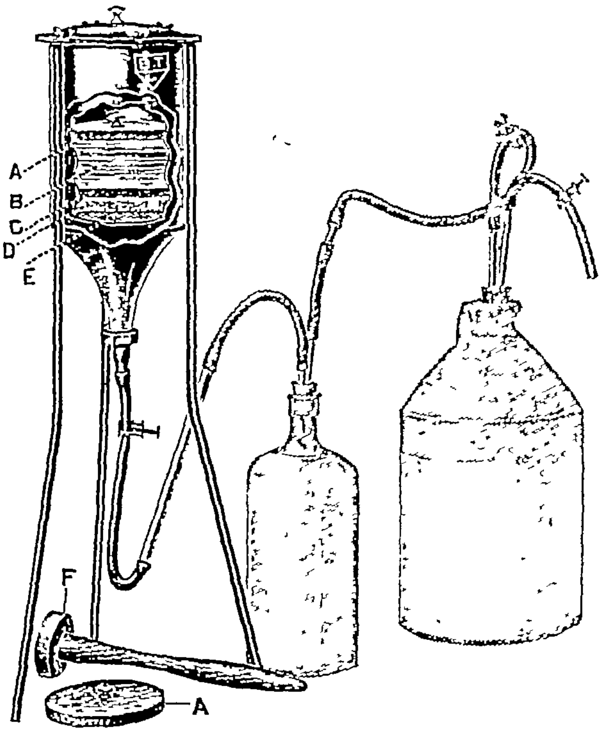
[1] Stanley Phillips (45, Brondesbury-road, London, N.W. 6): a collection of the latest publications of Messrs. F. A. Davis Co., Philadelphia; E. and S. Livingstone, Edinburgh; and Cassell's, London, including Hay's Diseases of the Ear, Nose and Throat; Sajous' Analytical Cyclopædia of Practical Medicine; Russell's "Ultra-Violet Radiation," and McKendrick and Whittaker's "X Ray Atlas"; and the "Practical Medicine Series of Year Books."—[21] H. K. Lewis and Co., Ltd. (136–140, Gower-street, London, W.C. 1): a selection of their publications, including L. R. Fifield's "Minor Surgery"; E. A. Barton's "Essentials of Infant Feeding"; B. Burnett Ham's "Synoptic Chart of Skin Diseases," and the second edition of W. Ironside Bruce's "System of Radiography"; the *Clinical Journal*; and a selection of card index systems, ledgers, case sheets, &c.—[58] Constable and Co., Ltd. (10–12, Orange-street, London, W.C. 2): a selection of publications, including a "Modern Methods" series; and "Towards Moral Bankruptcy," by Bureau.—[71] W. B. Saunders Co., Ltd. (9, Henrietta-street, London, W.C. 2): a number of standard works in all branches of medicine.—[75] John Wright and Sons, Ltd. (Bristol): the "Medical Annual"; the *Journal of Surgery*; new editions of many well-known handbooks; and various systems of bookkeeping.—[82] J. and A. Churchill (7, Great Marlborough-street, London, W. 1), celebrating their centenary this year, showed a number of new and standard works, including Beaumont and Dodds's "Recent Advances in Medicine"; Goulden's "Refraction of the Eye"; Jackson's "The Effects of Inanition and Malnutrition upon Growth and Structure"; and Koby's "Slit Lamp Microscopy of the Living Eye."—[85] The Oxford University Press (Amen House, Warwick-

square, London, E.C. 4): text-books on medical, surgical and allied subjects, including Price's "Medicine"; Leonard Williams's "Middle Age and Old Age"; Cope's "Clinical Researches in Acute Abdominal Disease"; and Taylor's "Neurological Fragments," by J. Hughlings Jackson.—[10] The Food Education Society (24, Tufton-street, London, S.W. 1) showed a series of pamphlets and books on food, cookery, and hygiene, including "The Gateway to Health"; "Rearing an Imperial Race"; "Facts for Patriots"; and "Puddings and Porridge."

New Inventions.

A NEW FILTER-PAPER PULP-HOLDER.

FOR several years one of us has used filter-paper pulp in an improvised holder for the purpose of filtering culture media and other fluids with invariable success. The chief feature of this pulp-holder is that as much as possible of the under surface of the pulp should be free for the passage of the filtered material. We have now devised the holder here illustrated designed to simplify the preparation of the filter.



1. For a filter of 6 in. diameter 4 oz. of dry filter-paper pulp is broken up in about two litres of water. It is then reduced to a state of very fine division by the hands or with a whisk. 2. Pour the prepared pulp into the filter-holder and allow the superfluous water to drain away. 3. Connect to the exhaust pump and filter bottle. Exhaust gently, in the meanwhile pressing the pulp down firmly and evenly with the rammer (F) until no more water is drawn through. 4. Cover the pulp (D) with about 1 in. of washed sand (C). 5. Place the float (A) on the sand. The float is of service because fluids poured on to it do not disturb the surface of the sand. 6. Draw through about a pint of water (hot water if jellies are to be filtered) to clear away any fragments of pulp which may have escaped through the gauge (E). When the water reaches the surface of the sand, clamp the tube connecting the filter with the exhaust pump. 7. Disconnect the filter bottle or flask, empty the bottle, and reconnect it to the filter. The filter is now ready for use. The procedure should not take longer than 10 to 15 minutes.

Procedure for Filtering.—1. Pour the fluid to be filtered on the float until the filter is full. If a jelly is to be filtered replace the remainder in the steamer until there is room in the filter. 2. Connect exhaust bottle by unscrewing clamp and exhaust gently. The water which was held in the pulp will come through first. By observing the glass connexion the filtrate can easily be seen to follow the water which was held in the pulp. At this point clamp off, empty filter bottle, reconnect, and exhaust again gently.

With a properly made filter, 5 to 6 litres of agar can be filtered in half an hour without the addition of egg albumin. By preparing the filter with two layers of pulp and sand alternately bacterially contaminated fluids or broth cultures can be freed of at least 90 per cent. of bacteria. When such fluids have to be passed through a germ-proof filter, a preliminary passage through a pulp filter represents a great saving of time and of filter candles.

Messrs. Baird and Tatlock have made the pulp-holder for us.

E. T. THOMPSON.
Orpington. E. CHARD.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. J. S. McGrath and Surg. Lt. H. C. C. Veitch are placed on Retd. List.

ROYAL NAVAL VOLUNTEER RESERVE.

The King has approved of the award of the Royal Naval Volunteer Reserve Officers' Decoration to Lt.-Comdr. E. Elgood.

Proby. Surg. Sub-Lt. H. O'Connor to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. G. O. Chambers retires, receiving a gratuity, and is granted the rank of Lt.-Col.

The undermentioned Majs. retire on ret. pay:—E. L. Moss and E. G. Anthonisz, and are granted the rank of Lt.-Col; M. Keane and G. H. Rees.

The undermentioned from Reg. Army Res. of Off. to be temp. Capts.: Lt.-Col. W. Owen-Prichard (and relinquishes the rank of Lt.-Col.), and Capt. S. Pinion (and relinquishes the rank of Capt.).

RESERVE OF OFFICERS.

Capt. A. G. Henderson, late temp. Capt., R.A.M.C., to be Lt.

MILITIA.

Capt. T. W. E. Elliott to be Maj.

TERRITORIAL ARMY.

C. E. Fenton to be Lt.

Capts. A. F. L. Shields (late R.A.M.C. Militia), H. F. W. Adams (late R.A.M.C.) and J. P. J. Jenkins (late R.A.M.C., Special Reserve) to be Capts.

2nd Lt. T. A. S. Samuel (late 15th Lond. R.) to be Lt.

ROYAL AIR FORCE.

Flight Lt. A. E. Henton relinquishes his temporary commission on ceasing to be employed and is permitted to retain his rank.

The undermentioned Capts., Army Dental Corps, are granted temporary commissions as Flight Lts. on attachment for four years' duty with the R.A.F.: M. J. O'Reilly, S. A. McCormack, and P. P. Hogan.

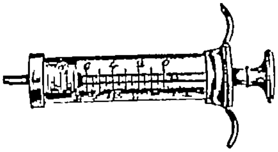
The undermentioned Flight Lts. (Capts., Army Dental Corps) relinquish their temporary commissions on return to Army duty: G. F. Charles, L. Somerville-Woodiwis, and J. H. W. Fitzgerald.

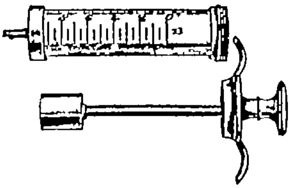
REGIONAL ANESTHESIA

Syringe, Needles, etc.,

as used by

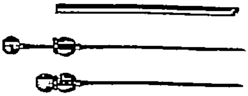
GASTON LABAT, M.D.





LABAT'S

Spinal Puncture Needles, used also for epidural or caudal block. One of the needles has its stylet partly out, showing the device by which the stylet is held in position after being introduced its full length The protective shield is shown separately



NEOCAINE

Corbière

For use in Regional Anesthesia:

Tube containing 2 capsules of 50 cgm - 3/-

For Intraspinal Block:

Special Ampoules containing 0·10 gram, per box of 12 - - - - - - - - 9/-

Special Ampoules containing 0·12 gram, per box of 12 - - - 10/-

Labat's Cardiac Stimulant (*vide* "*Regional Anesthesia*" p 440), per box of 12 ampoules - - 4/-

Less professional discount.

Needles, Nos.	1	2	3	4	5
Length, mm.	20	50	80	100	120
Diameter, mm.	0·6	0·7	0·8	0·9	1

Labat's regional anesthesia needles, provided with special bayonet lock hub. Note the slot on one side of the hub and the helix collar The needle on the right side is in its protective shield and has its stylet in.

‘BYNIN’ AMARA

Trade Mark

A Powerful Tonic and Hæmatinic

‘BYNIN’ AMARA is of special value in neurasthenia, particularly when associated with low blood pressure, anæmia and atonic dyspepsia ; in convalescence it gives that impetus which often enables the system to overcome the aftermath of disease and to recover completely.

‘Bynin’ Amara has important advantages over Easton’s-Syrup on account of its basis being ‘Bynin’ Liquid Malt in the place of syrup. The ‘Bynin’ Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

COMPOSITION

Quinine Phosphate - -	1½ gr.
Iron Phosphate - - -	2 ,,
Nux Vomica Alkaloids	
equal to Strychnine	1/16 ,,
‘Bynin’ Liquid Malt - -	1 oz.

DOSE 2 to 4 fluid drachms in water twice or thrice daily after meals.

Further particulars and free sample will be sent on request.

NEW LIGHT ON MUSCLE TONE.

A NOTEWORTHY feature of the study of diseases of the nervous system in recent years has been a return to more purely clinical and physiological methods of approach. This tendency is well seen in Dr. KINNIER WILSON's Croonian lectures on Some Disorders of Motility and Muscle Tone with Special Reference to the Corpus Striatum, of which the final instalment now appears in our columns. The Croonian lecturer is to be warmly congratulated on his survey of an admittedly intricate neurological problem; the space demanded for its elaboration was warranted by its practically helpful nature. It is no exaggeration to say that 20 years ago our knowledge of the functions and diseases of the corpus striatum was almost negligible, while our conceptions of disorders of motility in general and of muscle tone in particular were strictly limited. Since then an enormous amount of investigation, both clinical and pathological, has taken place, amongst which the original work of Dr. WILSON himself in identifying the syndrome now known as progressive lenticular degeneration (Wilson's disease) with disease of the corpus striatum must always hold a high place of merit. No one indeed is more fitted than he to throw light on the darkness of the general knowledge of this subject. But speculation and hypothesis have much exceeded ascertained facts in this as in other departments of medicine, and the student may well be disconcerted at the confusing nomenclature and theories which have been adumbrated. The various types and the sequelæ of epidemic encephalitis have, as is well known, added largely to the group of conditions in which disorders of motility and of muscle tone are commonly seen and attributed to striatal disease. The frequency in particular of the Parkinsonian syndrome as a sequel of this disease has provided opportunities of study of which Dr. WILSON has availed himself very fully.

Dr. WILSON's careful analysis of the symptoms of striatal disease as exemplified in the Parkinsonian syndrome may be compared with Prof. CRUCHET's University of London lecture, published in this issue, on the Relation of Paralysis Agitans to the Parkinsonian Syndrome of Epidemic Encephalitis. In many respects their opinions differ, as will presently be shown. The "paralysis," to use a general term, present in the Parkinsonian syndrome is considered to comprise three factors: (1) A relative motor weakness, most marked in those muscles whose mass is small; (2) a slowness of movement; and (3) a poverty of movements. The term "akinesis" is used to embrace these three symptoms, and the suggestion is made that part at least of this akinesis arises from an unwillingness to move, since in this disease movements require an unusual effort. One of the symptoms generally described as occurring in the Parkinsonian state is a loss or diminution of the so-called "associated" or "automatic" movements. Such movements Dr. WILSON prefers to call movements of coöperation, and he is at pains to show first that these sorts of movements are not in reality lost, and, secondly, that to argue from their supposed absence the existence of a centre for such movements in the corpus striatum is a fundamental mistake. With his opinion on this point we are in entire agreement. The general opinion that there is an increase in muscle tone in these disorders is upheld by the lecturer, though the relation between the increase in tone and the loss of movements is not constant. We cannot here follow the lecturer in all his arguments, but the reader will note with interest that Dr. WILSON disagrees profoundly with HUNTER's recent conclusions as to the existence of a condition of plastic tone in the Parkinsonian state. Involuntary movements of different kinds are usually held to hold a place in the symptomatology of diseases of the corpus striatum. The principle laid down by HUGHLINGS JACKSON is recalled that positive symptoms, such as involuntary movements or tremor, cannot be directly caused by a purely destructive lesion. Such symptoms may be due to irritation or they may constitute what is now known as a "release phenomenon"—that is, the incoördinated or unqualified action of certain neural mechanisms when released from the normal control of the mechanisms which have been destroyed. The problem, therefore, is, as Dr. WILSON suggests, not what mechanisms are paralysed but what are active. Regarding the involuntary movements of chorea, Dr. WILSON has made the interesting observation that in many cases he found an interruption of the normal reciprocal innervation of muscles. He considers that a relative integrity of the pyramidal or cortico-spinal tracts is essential for the appearance of true choreiform movements, an opinion which receives strong support from the established clinical fact that the greater the amount of paralysis in chorea ("limp chorea") the less is the amount of movement present. No sharp distinction can be drawn between the movements of chorea and those of athetosis, and it is natural to postulate a similar cause for the two conditions. Dr. WILSON's arguments lead to the view that both chorea and athetosis have their origin in some afferent disorder of regulation, attributable to lesions of the cerebello-mesencephalo-thalamo-cortical path, from which conclusion the conception of an involuntary cortical motor activity follows.

The pathogenesis of tremor has long been a matter of dispute. Few probably will gainsay the view that it must be regarded as a release phenomenon of some kind. In Dr. WILSON's view it differs fundamentally from chorea and athetosis, if only because in tremor the normal reciprocal innervation of muscles is still found, while in chorea and athetosis it is wanting. His conclusions are so interesting that they may be here repeated. "Tremor is an involuntary movement belonging to the old motor system (infracortical subpallial), while choreo-athetosis is an involuntary movement of the new (cortical pallial) system." Prof. CRUCHET's close clinical studies of the features of the post-encephalitic Parkinsonian state and of paralysis agitans have led him to the conclusion that the two conditions are entirely different, a view which we think few neurologists in this country will support. His description of what he calls the bradykinetic syndrome approximates very closely to the akinesis of Dr. WILSON. But where he differs profoundly from most authorities is in his denial of the existence of any true rigidity or muscular hypertonus in the Parkinsonian state, an opinion in which we confess ourselves unable to follow him, though with many of his differential points in diagnosis between paralysis agitans and the post-encephalitic Parkinsonian state we are in full agreement. We feel that these Croonian lectures should be of service in disentangling essentials from a mass of confusing hypotheses, which have been erected on an unstable base of unconvincing attempts in the correlation of clinical symptoms with the facts of morbid anatomy. In the unravelling of the problems of disease of the human nervous system the clinical method must always hold the first place and the value of these lectures as an example of close and unbiased clinical studies is great. They should serve to quicken interest in a difficult subject and rouse the possibly flagging spirits of any who may have been led to think that the day was past when purely clinical methods could achieve progress.

◆

FOOD SOPHISTICATION IN 1924.[1]

The sophistication of food is a tempting form of deceit, and the last report of the Ministry of Health shows that it has not lost its attraction for various trades. When the purveyor causes 2 lb. of sugar to appear where only 1 lb. grew before he is expressing his impulse to cultivate; in selling them by misrepresentation he is educating his wits; financially he is satisfying his acquisitive instincts. But these considerations do not appeal to a public which expects a pure food-supply. Wherever and whenever found such offenders should be treated in accord with their demerits, and it is matter for satisfaction that in this country to-day their careers are becoming precarious. Under the administration of the Sale of Food and Drugs Act there has been an increased activity on the part of many local authorities during 1924. The total number of samples analysed was 118,000—an increase of 3154 over the previous year—and, either as a result of rising interest in the subject or because of an improving moral atmosphere, the percentage of adulterations showed a slight reduction. A total of 6987 samples, or 5·9 per cent., was reported as adulterated or not up to standard, and, although this figure is very large, it compares favourably with the records of 1923 (6·1 per cent.) and 1922 (6·2 per cent.).

Milk was as usual the chief object of analysis, and of 62,133 samples which were purchased and submitted for analysis 7·7 per cent. were regarded as adulterated or not up to standard. This did not represent any improvement on the figure for 1922 and virtually none on that for 1923; but there were only 160 samples described as contaminated with dirt, as against 197 in 1923, which suggests that the efforts of the Ministry of Agriculture and other cognate bodies towards securing a clean milk-supply are proving effective. In 25 cases successful legal proceedings were instituted against vendors of dirty milk, and the cynical may note with relish that on Sundays there is more tampering with milk owing to the greater demand and a feeling of greater immunity from interference. Samples procured on Sundays in the county of Durham showed adulteration in 27·6 per cent. of cases, although the figure for all the specimens collected throughout the year was only 15·5 per cent. The addition of colouring matter is infrequent. Altogether 68 samples were reported against on account of such additions, and in 33 cases fines or costs were recovered; but in spite of the considerable number of prosecutions against milk-sellers, only two were prohibited from further carrying on their trade. As the fines inflicted were usually not large, it would seem that in all punitive proceedings reliance has been chiefly placed on the publicity which is given to the guilt. Over 10,500 samples of butter were analysed during the year, but of these only 1·4 per cent. were condemned as not up to the requirements of the Act. Loading with water is the most common treatment, and 74 samples contained water in excess of the maximum of 16 per cent. legally permitted. Foreign fats, such as margarine, were found in 68 samples, and in nine there was more than 0·5 per cent. of boric acid. At Leeds an informal sample of butter was purchased by the police from a hawker in the street. It was submitted to the public analyst, who reported that it was wholly margarine, and the vendor was sent to prison for three months for obtaining money under false pretences. Special interest has been taken in condensed and dried milks on account of the recent regulations dealing with them. A larger number of samples than usual was taken; but it was found that the percentage reported against remained about the same. Some were deficient in fat; three were contaminated with lead, and a good many were sold in tins bearing labels not in accordance with the law; but as the majority of the cases were first offences the local authorities generally contented themselves with cautioning the vendors. The sale of boricised cream without proper notice to the purchasers is still remarkably common. Altogether 196 out of 1089 samples bought as fresh cream contained boric acid, and 24 out of 1016 samples bought as preserved cream contained boric acid in excess of the maximum of 0·4 per cent. allowed. It may be observed in this connexion that the Committee appointed in 1923 by the Minister of Health to consider the uses of preservatives has advised the total prohibition of boron derivatives in food. Their cumulative action is obscure, but appears to be harmful, and from the practical aspect the Committee was convinced that they could be dispensed with in food without serious inconvenience to traders or consumers.

From the reports it would appear that the more unregenerate days of the "wicked grocer" are passing. A sugar adulteration of 0·3 per cent. of cases in 1924 is, comparatively speaking, negligible. The grocer is gaining a vindication from Mr. Chesterton's assertion that

> "He sells us sands of Araby
> As sugar for cash down."

Full-blooded poets are apt to belittle the grocer, and cry up mine host at the inn, so that the grocer may smile at the discovery that the righteous minds of innkeepers have led them in 13·5 per cent. of cases to adulterate their spirits. Two defendants charged with selling diluted spirits based their defence on notices exhibited in their bars advertising that the alcoholic strength of their wares was not guaranteed; but the ruling went against them on the ground that the article supplied was not of the nature, substance, and quality demanded. The display of notices in bars appears to be relatively inefficient. Not all grocers, however, have abandoned subtlety, and there has been some doubt in various places whether dyed and flavoured maize can legitimately be labelled as custard powder. Furthermore, several jam manufacturers have been prosecuted: one of them was fined £20 and ordered to destroy 1400 lb. of his produce, and another, whose strawberry jam contained not less than 75 per cent. of apple jelly but not one whole strawberry, had to pay a similar fine and costs. It is obvious from this information that the present machinery for detecting and displaying fraud is of great importance. Though it would be unwise to argue that the reduction of adulterated samples in two years from 6·2 per cent. to 5·9 per cent. indicates that in 40 years dishonesty will have been abolished in this country for ever, it may nevertheless be admitted that the outlook for the future is encouraging. In the meantime the machinery requires local support and extension.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

THE Fifth International Congress of the History of Medicine was held at Geneva from July 20th to the 24th under the presidency of Dr. Charles Greene Cumston, lecturer in the history of medicine at the University of Geneva, with Sir D'Arcy Power as president of honour. The meetings, which were held in the Athénée, were well attended, representatives being present from Belgium, Cuba, Denmark, France, Great Britain, Holland, Italy, Morocco, Poland, Spain, Switzerland, and the United States. Opening addresses were delivered by the President of the Congress, the President of the Medical Society of Geneva, the representative of the Council of State, the rector of the University of Geneva, and the President of the International Society of the History of Medicine, and were followed by a lecture by Prof. Eugène Pittard, illustrated by lantern slides, on operations in the Stone Age. Special mention should be made of Dr. Cumston's address, which contained an account of the distinguished Geneva physicians Daniel Le Clerc, whom Dr. Cumston described as the father of the history of medicine, Jean Antoine Sarasin, the writer on plague, and Théophile Bouet, the morbid anatomist. In the evening the members of the Congress were entertained by the President and Mme. Cumston at the Hôtel des Bergues, where a concert terminated with the delivery of an ode specially prepared for the occasion in honour of the medical profession. On July 21st the principal papers read were one by Sir D'Arcy Power on the Disputationes chirurgicæ selectæ, or early eighteenth century theses, edited by Albrecht von Halle, and one by Dr. J. D. Rolleston on Voltaire and English doctors, particularly Cheselden, Mead, Hans Sloane, Friend, and Towne, the author of a work on diseases in the West Indies and translator of part of La Henriade. Dr. John Comrie lectured on the eighteenth century neurologist, Robert Whytt, who gave the first clear description of tuberculous meningitis; Dr. Guisan, of Lausanne, on Fabricius Hildanus, the celebrated surgeon of Basle; Dr. J. G. de Lint on a letter of Tronchin dealing with the Suttonian method of inoculation; Dr. Ernest Wickersheimer on the presence of syphilis at Geneva at the end of the fifteenth century; and Mr. C. J. S. Thompson on hygiene in early civilisations. In the afternoon a garden party was held in the grounds of Dr. and Mme. Rilliet's house at Vongeron, where, in addition to an admirable view of the lake and of Mont Blanc, the members of the Congress had an opportunity of inspecting the library of Dr. Frédéric Rilliet, the author of the well-known work written in collaboration with Barkez on diseases of children, and of meeting the veteran pædiatrist, Prof. D'Espine, whose resemblance to the late Sir Clifford Allbutt struck several of the British members present. On July 22nd papers were read by Dr. R. O. Moon on Paracelsus and medicine, by Dr. E. B. Krumbhaar, of Philadelphia, on the medical literature of the seventeenth century as exemplified in the Elzevir Press, by Dr. H. Renaud, of Rabat, on some recent acquisitions to the history of Arabian medicine in Morocco, by Dr. Tricot Royen on the history of lepers at Antwerp and Louvain, by Dr. Wickersheimer on the surgeon Jean Gispaden, who flourished at Grenoble and Annecy at the end of the fifteenth century, and by Mrs. Lilian Lindsay on the growth of dentistry in England from the earliest times to the beginning of the nineteenth century. The afternoon meeting was followed by a visit to the Rousseau Museum and the University library, where a number of rare works were on view. In the evening the Congress was received by the administrative Council of the city of Geneva at the Palais Eynard.

On the following day the Congress made a tour on the lake and visited the Castle of Chillon, when the medical profession of Montreux provided lunch, and then to Evian-les-Bains, where a banquet was offered by the administration of the spa. On the 24th Dr. Wierzbicki read a paper by himself and Prof. A. Wrzosek on auscultation in Poland during the first half of the nineteenth century. Dr. J. W. Courtney, of Boston, dealt with Dr. Benjamin Waterhouse, "the *Jenner of America*," Dr. De Alcardo of Madrid, exhibited the iron crown used in the middle ages as a cure for certain diseases of the head, and Dr. Bugiel described the life of the Polish students at the Paris Faculty of Medicine in the thirteenth, fourteenth, and fifteenth centuries. Mr. C. J. S. Thompson, in the absence of the writer, read Dr. J. B. Hurry's paper on I-Em-Hetep, prime minister to King Zoser, and afterwards the medical god of Egypt. The secretary of the Congress, Dr. de Peyer, contributed a communication on his ancestor Jean Conrad Peyer, the anatomist and physician of Schaffhausen. The Congress terminated in the evening with a banquet at the Hôtel des Bergues.

The next Congress will be held at Leyden in the last week of July, 1927, under the presidency of Dr. J. G. de Lint.

Annotations.

"Ne quid nimis."

COMFORTABLE WARMTH FOR MENTAL WORKERS.

RESEARCHES[1] carried out by Margaret Fishenden, D.Sc., and R. E. Willgress, B.Sc., on the heating of rooms for sedentary workers indicate that the most comfortable conditions for mental work correspond with an air temperature of about 55° F. in conjunction with the requisite intensity of radiation for warmth; that is, a source of radiant heat with a horizontal component of radiation equivalent to 75 British thermal units per square foot per hour, over the position occupied by the worker. In their work these authors used a room of about 4000 cubic foot capacity, and compared three sources of radiant heat: (1) gas fire, (2) electric heater, (3) low-temperature (up to 750° F.) specially-designed heater (6 ft. square), consisting of a shallow sheet-iron box with asbestos back and baffled interior almost filling the hearth opening and heated internally by a series of Bunsen flames playing upon an arrangement of refractory material. They preferred this low-temperature heater because it gave a more uniform distribution of radiation with height, the degree of comfort being greater than with either of the other two radiators. They found that with slightly higher air temperatures than 55° F. —e.g., 58° or 59° F.—a feeling of mental lassitude was produced, although radiation was still required to maintain warmth without physical exertion. Below 51° or 52° F. draughts or the effects of low air temperature became very perceptible, and the typical "scorched on one side, chilly on the other" sensations associated with open-fire heating in cold weather could be felt.

It is the relatively equable climate in Great Britain which renders open-fire heating practicable. Where long cold winters are experienced—e.g., the Continent, America, and Canada—open fires have to be abandoned as they do not supply sufficient air heating when the outside temperature is below 45° F., so that closed stoves or central heating are more generally used under these conditions. The authors deal also with air-heating systems, the air being heated either by hot-water radiators, or by ordinary luminous-flame bat's-wing gas burners arranged at suitable intervals around the room at a level of about six inches above the floor. Under such air-heated conditions without any source of radiant heat, an air temperature of about 65° F. is required to produce comfort; this means that the surrounding surfaces must also be at 65° F. and the air velocity very low (about ¼–½ ft. per second even near the floor). It is considered that with a surrounding temperature of 65° F. and ordinary clothing, the human body at rest is able to get rid of the heat produced therein by convection, radiation, and minimal evaporation. Comfort is thus maintained, but these conditions are not so favourable for mental work as when the air temperature is 55° F. and the extra heat supplied by a source of radiant energy. Of course, the air changes by draught up the flue are great with radiant heaters in the hearth, so that there is considerable movement of air in the room. Dr. Leonard Hill has long advocated the avoidance of stagnant air in rooms chiefly because of infection and monotony. He has pointed out in many of his researches that for health and mental alertness, ventilation by open fire and open window is the best in small rooms in this country. The present research confirms this view.

---

[1] Department of Scientific and Industrial Research. Fuel Research Board, Technical Paper No. 12 The Heating of Rooms: A Comparison of the Costs of Different Methods on the Basis of Warmth Comfort. By Margaret Fishenden, D.Sc., F.Inst.P., assisted by R. E. Willgress, B.Sc., A.R.C.Sc. H.M. Stationery Office. Pp. 48. 1s.

Dr. Fishenden and her co-worker studied also the effects of draughts produced by electric fans. With air velocities of 2, 4, 6, and 8 ft. per second respectively, over the position of the observer dry-bulb air temperatures of 69° F., 72° F., 75° F., and 76½° F. were necessary to sustain warmth, in the absence of radiant heat. They found, however, that with draughts exceeding about 4 ft. per second the movement of air was annoying and detracted the attention from mental work. Of much practical value are the findings of these authors with regard to cost of heating. They calculate from their experiments the cost of different methods for imaginary rooms of 1000, 2000, and 4000 cubic feet respectively, and with occupants up to six in number. For continuous heating in small rooms, hot-water radiators fed from a coke-fired boiler are the most economical; but as the size of the room increases open coke or coal fires become cheaper, especially when there are only a few people in the room. This is because when air heating is employed the whole room must be warmed, however few the occupants, whilst with heating by radiation people can gather around a small fire whatever the size of the room. For intermittent heating, say, when a room is used only for four hours a day, hot-water radiators remain the cheapest for small rooms with more than one or two occupants, but for larger rooms, especially when sparsely occupied, open coal or coke or gas fires become cheapest. For longer periods of use the advantage of open fires over air heating is less pronounced; for shorter periods it is more pronounced. In larger rooms where people cannot gather round the fire, hot-water radiators are usually the cheapest method of heating.

From the health point of view, air heating with stagnation of air in the room is not desirable; and in practice it is often found that conditions of ventilation which appear to favour economy are by no means the healthiest. Thus the poor huddle together with much overcrowding, especially in winter. In China the natives cook their food by means of a fire under a brick platform and use the platform thus warmed as a sleeping couch at night. For many the cost of heating will remain a matter of greater consideration than the acme of hygiene. With the ever-increasing cost of fuel in this country these investigations of the Fuel Research Board have an immediate practical application.

THE DICK TEST.

THE admirable work of Dr. George F. Dick and Dr. Gladys H. Dick on scarlet fever has been followed in this country with keen interest. In January, 1924, they described their skin test for susceptibility to that disease, and in the following month a method of active immunisation. These successes were the result of a number of years of painstaking work and the experimental production of scarlet fever in the human being. In a recent paper[1] they resume this work, and cite further evidence of the production of immunity to scarlet fever. Accurate standardisation of the scarlet fever toxin is essential, and the Dicks state that on testing samples of skin-test solutions from various sources they have found them ranging from one-fourth to four times their proper strength. They believe that a positive reaction may be produced in immune persons by injecting a larger test dose, and that negative reactions may be obtained in susceptible persons by reducing the dose; further, that some skins react with papule formation to intradermal injection of mere sterile salt solution. In order to avoid confusion from this, and from the small reddened area which may be caused by the added preservative, the skin-test dose was so graded that an area of reddening of less than 1 cm. in all diameters is regarded as a negative reaction. On the other hand, an area of reddening, however faint in colour, measuring 1 cm. or more in any diameter, is considered a positive reaction. If the reaction has entirely faded at the end of 24 hours they regard it as negative.

In this country a number of observers have been engaged in testing the Dick susceptibility reaction with results in the main conforming to those obtained in America. Little, however, has been done in attempting to produce active immunity to the disease. The technique for the Dick test is the same as for the Schick test, but it is worthy of note that when the fluid is injected a little more deeply into the skin than it should be, the Dick test is liable to fail where the Schick reaction would appear. Several dilutions of the toxin have been used for experimental purposes, the amount of fluid injected into the skin being kept constant at 0·2 c.cm. The reaction has been found to vary in intensity, in the size of the erythematous area, in its time of appearance, and in the time it lasts. With a dilution of the toxin of 1 in 1000 the Dick reaction appears as an erythematous area (seldom indurated) arising at the site of injection, the erythema varying in intensity in a way comparable to the various tints seen in the different rashes of scarlet fever. The size of the erythematous area varies considerably, but usually measures from about three-quarters of an inch to rather over an inch in diameter. In the experience of Dr. F. Thomson at the North-Eastern Hospital the interval from the time of injection to the commencement of the erythema has averaged from five to six hours, but it may be postponed for 24 hours, and has been observed within two hours. The average duration of the erythema has been about 40 hours, and in two instances only was it under 24 hours. One of these had disappeared in 13 hours when rubbing re-elicited the erythema, which then lasted a further two days. With higher dilutions of the toxin—e.g., 1 in 6000, when injected alongside the 1 in 1000 dilution on the same person—the resulting reactions have been found not infrequently to be as large as with the dilution of 1 in 1000, but their duration was less—seldom lasting 24 hours.

Evidently more work remains to be done before the value of the Dick test can be assessed, but a certain amount of optimism seems to be justified. The occasional failure of the test, when failure is not to be expected, serves at times to create disappointment, but the difficulty in standardising the toxin and the possibility of faulty technique in carrying out the test must be remembered.

---

[1] Journal of the American Medical Association, May 16th, 1925.

meantime it might be well to avoid defining too closely what or what is not a positive result, and to keep exact records of the reactions. The question to which we should like an answer is: Does a positive Dick reaction show that an individual is susceptible to scarlet fever and does a negative result show that he is not? And the answer is not yet forthcoming.

SUBSTITUTED UREAS IN TRYPANOSOMIASIS.

The undoubted value of the substance known as "Bayer 205," and the obscurity which has hitherto shrouded its constitution, have resulted in focusing attention on its chemical constitution. Since 1923 work of investigation has been carried out in the laboratories of the British Dyestuffs Corporation on the synthesis of certain ureas and their effect upon trypanosomes. The idea of working upon these ureas was suggested by the numerous German patents which had been taken out relating to such bodies, and by a formula, suggested by King in 1921, in which he indicated that the urea was built up by joining two chains which each contained two *p*-amido benzoyl residues. In a paper[1] published in the *Journal of Pathology and Bacteriology* T. H. Fairbrother and others have described in detail the preparation of three ureas and the investigation of their effect on trypanosomes. The trypanocidal action of these substances has been examined by ascertaining the action upon mice infected with *Trypanosoma equiperdum*. This organism is similar to the one which Wenyon employed in estimating the effect of "Bayer 205" in 1921. As a result of their work these investigators were able to show that there is definite evidence of trypanocidal properties in the substituted ureas, which are entirely dependent on the configuration of the molecule and on the groups which go to form it; but the only one of the three synthesised ureas which showed marked trypanocidal properties was the one built up on the formula of Fourneau. This substance is the urea from meta-aminobenzoyl para-methyl meta-aminobenzoyl amino-naphthalene tri-sulphonate 4 : 6 : 8. Whilst the trypanocidal action of this urea in vivo requires further investigation, it has been found that on injection into a mouse its tolerated dose is 10 mg. per 20 g. mouse. The curative dose is as low as 0·05 mg., and this makes the ratio of curative to tolerated dose of 200 : 1.

EXPERIMENTAL PNEUMONIA.

Pneumococcus pneumonia remains one of the serious infective diseases, and it is singular as being the only bacterial infection in which a knowledge of the causative agent has not resulted in any perceptible reduction in mortality. The isolation of the several types of organisms has done something; the discovery that the form of coccus which so many normal people harbour in their throats is not usually the form which causes fatal pneumonia has partly, but by no means wholly, explained one of the mysteries of the disease; serum therapy has saved some lives, but it has not come into that wide use which guarantees the substantial utility of a remedy. Progress has been disappointing and the state of affairs at present is highly unsatisfactory. Any further knowledge of the relationship of the organism to the lung is therefore welcome, and those who are interested in the subject will find in the current number of the *Journal of Pathology and Bacteriology* (1925, xxviii., 427) an illuminating paper by Dr. J. F. Gaskell, of Cambridge, on the results of infecting rabbits by insufflation. He worked with a single strain of pneumococcus, the virulence of which varied spontaneously or was deliberately altered during the course of his observations, and his main point is that the effect varies with the virulence and not with the dose. With cultures of low virulence broncho-pneumonic lesions are produced, generally near the root of the lung and strictly localised to the areas originally infected; the animal recovers. With higher virulence localisation is less effective, and by coalescence a lobular pneumonia arises which may extend to pleurisy; with a further increase the whole lobe is involved, giving a true lobar consolidation, often with pleurisy and pericarditis. Finally, with very virulent organisms, an intense fatal septicæmia is obtained with a characteristic miliary lesion throughout both lungs—the lesion, that is, which is produced by subcutaneous inoculation. It will be seen that these results are in accord with the views previously published by Dr. Gaskell and Dr. R. R. Armstrong that the differences between broncho-pneumonia and lobar pneumonia in man are essentially relative rather than absolute, and depend mostly on the ability of the lung to localise the original infection by an inflammatory reaction. We seem to have here evidence that the progressive spread of severe acute lobar pneumonia, which is so striking a feature of the disease anatomically and clinically, is due to the qualities of the pneumococcus rather than those of the lung involved. The suggestion that dose is relatively unimportant corresponds well with the experience that overcrowding, which is the great practical factor which determines dose in respiratory infections, has little to do with the occurrence of the disease.

RESEARCH ON DISTEMPER.

Some years ago the resemblance between distemper and influenza associated in a common effort those who love their fellow men and those who see in them only one more reason for admiring dogs. Since 1923 the Medical Research Council has coöperated in the work on distemper undertaken by the *Field*, and at specially constructed premises near Mill Hill much has been done under a technical committee nominated by the Council. The special study of filterable viruses associated with distemper was entrusted to Dr. P. P. Laidlaw, with the coöperation, in particular directions, of Mr. C. C. Dobell, Dr. W. E. Gye, and Mr. J. E. Barnard, and it is greatly to be hoped that the conclusions reached, or at least the methods devised, by the two last in their work on cancer may prove of value in elucidating distemper. In the meantime, however, much necessary preparatory work has been done, and useful knowledge has been acquired about the propagation and spread of the disease. Its contagion is remarkably easily conveyed—e.g., by the hands, boots, or clothing of persons who have been in contact with dogs suffering from the disease—and it was necessary to erect elaborately insulated buildings in which to carry out the experiments. A fence which cannot be climbed surrounds them, and in the wall of the compound is a cleansing room which is the only means of going in or out, and in which all who enter must abandon their garments, take a bath, and put on sterilised clothes. The exact risk of the carriage of infection by flies is still unknown; but, although it has not been possible to protect all the kennels from them, their exclusion from the hospital is strictly enforced. It has been difficult to provide a supply of dogs perfectly free from infection and free from any acquired immunity. To produce these "clean" and susceptible subjects several generations have been bred under controlled conditions, and the investigators are now suitably supplied. Canine distemper, however, occurs in ferrets, and the use of these animals, which should be popular with rabbits, has led to economy in effort and expense. Moreover, it is hoped that a mild form of virus may be obtained from ferrets which will be useful in producing immunity in dogs. The *Field* should have high appreciation in the medical profession for its contribution to this sound and important work. Apart from the ever-present chance of research on one subject throwing light on another, the fact that man has modified canine evolution and fashioned the races of dogs in accordance with his own ideas to be his servants and friends, makes him responsible for compensating them out of the fruits of his increasing knowledge.

[1] Jour. of Path. and Bact., vol. xxviii., 1925, by Thos. H. Fairbrother, M.Sc., F.I.C., F. A. Mason, M.A., Ph.D., F.I.C., W. H. Perkin, F.R.S., and Arnold Renshaw, M.D., D.P.H.

MEMORIAL TO THE LATE DR. HERBERT WILLIAMSON.

ALTHOUGH he died in the plenitude of his powers, Dr. Herbert Williamson had been for nearly 20 years a member of the staff of St. Bartholomew's Hospital, where it was early recognised that he had beyond other men the gift of imparting knowledge. The proposal is therefore peculiarly fitting to establish a memorial to him in the hospital itself, and it is made with the full approval of the medical council of the hospital. The form which the memorial takes must depend upon the sum subscribed, but it is hoped that at least a sufficient amount may be secured to endow a bed in the department in which he worked. Subscriptions from Dr. Williamson's former colleagues, students, and friends may be sent to Mr. J. Barris, F.R.C.S., 50, Welbeck-street, London, W. 1.

THE PRICE OF GOVERNMENT ISSUES.

ON the occasion, some three years ago, of the publication of the Annual Reports of the Registrar-General for England and Wales and for Scotland, we remarked on the high and increased price demanded for these valuable issues. We were moved to comment by the fact that the preliminary figures issued by the Registrar-General at that date happened to be of vital interest to all public health authorities, so that a restricted circulation, due to high cost of purchase, could only be regarded as of real public disadvantage. Especially did it seem that the prices demanded would constitute a distinct penalty upon public health officers, while it was urgently important that these officers should have them under their hands for reference—indeed, all medical men requiring to verify the statistical bases of their work should have access to them. We learn therefore with pleasure of certain circulars from the Ministry of Health, admitting that the price of the Registrar-General's statistical reviews has been a subject of real concern to the Ministry, and proposing to mitigate the situation in important directions. The effect of the circulars is to offer the "Tables Part I—Medical" and "Text" volumes of the Statistical Review to public authorities and medical officers at a reduced price of 12*s.* 6*d.* per annum (instead of £1) on condition (1) that a subscription is taken up for five years and (2) that a sufficient response is received to justify an enlarged edition. The authorities are also informed that it is within their power to incur expense in providing the volumes for the use of their medical officer.

Even when protesting against the price demanded for these publications we were aware of the difficulty in which the Ministry were placed and would be placed, by the attempt to lower the figure, and we are not surprised to learn that even at the present prices the publication entails a heavy loss on the Exchequer. We have here the position with which publishers of scientific works are always faced, for in the nature of things they are dealing with two irreconcilables—the cost of production must be very high because of the special character of the work, and for the same reason the circulation cannot be widespread. But drastic curtailment in the scope of such work is the last thing that the medical profession or the public services would desire. Economy at such a cost would be disastrous. The only practical policy is to increase in every way the circulation, for no one would consider as a practical proposition the whittling down of the information contained in the reports until their practical utility was gone. The absence of a sufficient number of purchasers is the key to the situation, but it can hardly be expected that public health officers will find at their private expense the money to buy documents required in discharge of their public duties, especially when the sum required is considerable. The indication from the Ministry of Health to the local authorities that they have legal power to purchase the Statistical Reviews for the use of their medical officers removes at once an obstacle to a more general employment of these volumes, and in this way helps to solve the problem. The special price will not be confirmed until it is seen whether sufficient support is forthcoming, and the responsibility is now with the public health authorities and services for accepting the welcome opportunity offered. As is suggested above, the volumes are of obvious use to others besides those for whom the new arrangement has been designed especially; not only official departments and medical practitioners, but the public, through public libraries, may be moved to be purchasers, and by swelling the bulk of the circulation bring down the price of the volumes to a lower level.

POST-GRADUATE EDUCATION IN LONDON.

THE Minister of Health has appointed a Committee "to draw up a practicable scheme of post-graduate medical education centred in London." The Committee, whose chairman will be the Minister of Health himself, is constituted as follows: Lord Dawson of Penn, Sir Humphry Rolleston, Sir John Bland-Sutton, Sir Thomas Horder, Sir George Newman, Sir George Blacker, Prof. Hugh MacLean, Dr. R. A. Bolam, Dr. H. G. Dain, Mr. H. J. Paterson, Dr. J. Parkinson, Dr. H. L. Eason, and Mr. A. E. Webb-Johnson. The appointment of this Committee follows closely on the visit to this country of the Inter-State Post-Graduate Assembly of America, when Dr. Charles Mayo repeatedly advocated the foundation in London of a graduate school which should draw students from all quarters of the English-speaking world.

MEDICINE AND THE LAW.

Case of Alleged Malpraxis: Withdrawal of a Claim.

AN interesting case was recently heard before Mr. Justice Fraser, when damages were sought from Dr. R. G. Clements by an employee in the tramways department of the Manchester corporation for alleged malpraxis. The plaintiff had been attended for rheumatism, and his statement was to the effect that he had suffered no pain in his eyes until the doctor's assistant "flicked some powder from a box into them." Medical evidence for the defence showed that the plaintiff's condition could not have been caused by the drug, but that rheumatism, for which the plaintiff was first treated, and his eye-trouble were due to the common cause of an autogenetic poisoning. The defendant gave evidence, supported by specialists, to the effect that the general condition of the plaintiff and the condition of the eyes were due to a focus of poisoning which affected different parts of the body at different times, and before the medical evidence for the defence was completed the plaintiff's counsel intimated that he did not consider it right to go so far as to leave the case to be decided by the opinion of a jury. He withdrew on plaintiff's behalf every aspersion of any kind against the defendant, the proceedings having been brought under a misconception of the facts. The judge, in directing the jury to return a verdict for the defendant with costs, stated that there was not the slightest foundation for any suggestion of negligence, that it had been made abundantly clear that there were no grounds for any of the imputations, and that the course taken by counsel for the plaintiff was one that would have been expected from one of such legal experience.

The case is of importance to the medical profession as it illustrates the tendency on the part of patients to jump to conclusions on medical subjects without having the necessary knowledge to support the conclusions. The conduct of the defence was entrusted to the Medical Defence Union.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXIV.

THE TREATMENT OF PSEUDOCOXALGIA.

THE rationale of the treatment of pseudocoxalgia cannot be readily understood without a clear understanding of (1) the nature of the disease, (2) the various suggested causes, and (3) the clinical signs which vary in each phase of the process. As will be seen, treatment is different in the different phases.

Nature of the Disease Process.

Pseudocoxalgia is a condition of the hip-joint commencing in young children between the ages of 5 and 10, until recently not distinguished from tuberculous disease, and identified by means of serial radiograms which show a characteristic cycle of changes in the head and neck of the femur. Clinically, radiographically, and for the purposes of treatment, pseudocoxalgia may be divided into three stages named according to the predominant change in the head of the femur as seen in the X rays. Normally, in the child, the head of the femur consists of a cartilaginous envelope enclosing a bony nucleus. In the X rays the bony nucleus appears as a dense shadow. The surrounding cartilaginous envelope casts no shadow, but its extent can be judged by the clear space shown between the head of the femur and the acetabulum. The changes of pseudocoxalgia concern both the bony nucleus and the cartilaginous envelope.

In *Stage 1*, the stage of flattening, the head of the femur retains its normal shape as a whole, but the bony nucleus becomes smaller; there is more cartilage and less bone in comparison with the normal. Not only is the bony nucleus smaller but its density is irregular; in parts it is more, in others less opaque than usual.

In *Stage 2*, the stage of fragmentation, the cartilaginous envelope becomes flattened; it is no longer hemispherical but is spread out over a wide area and the neck on which it sits expands to accommodate it. The ossific nucleus becomes fragmented and in places disappears completely. It is as though the strength of the head of the femur has departed with the disappearance of the bony nucleus, and as a result the cartilaginous envelope has been flattened out by the superimposed body-weight of the patient.

In *Stage 3*, the stage of repair, the cartilaginous envelope retains the flattened expanded form it acquired in stage 2, while the bony nucleus gradually re-forms until a final stage is reached when the ossific centre has filled out the misshapen cartilaginous envelope, leaving only a narrow peripheral margin of cartilage. The time necessary for the completion of this cycle of changes—flattening, fragmentation, and repair—is uncertain. It is usually considered that two or three years elapse before repair is established.

Ætiology.

A number of different causes have been suggested to explain the changes of pseudocoxalgia; of these only two need here be considered—viz.: (1) That pseudocoxalgia is a mild inflammatory condition affecting the head of the femur. The arguments against this are many: Often the condition is without symptoms at any stage, and in nearly every case is symptomless in stage 1. In contra-distinction to inflammatory conditions, such as tuberculous disease of the hip-joint, the radiographic changes precede the clinical signs. Microscopic examination reveals no evidence of inflammation. Abscess formation is unknown. The blood count never shows a leucocytosis. The Pirquet test is usually negative and the Wassermann test is invariably negative. (2) That the condition is due to trauma. The traumatic theory best explains the sequence of changes in the head of the femur. This theory supposes that, following a mild trauma, the blood-supply to the epiphysis is damaged, and the bone cells, deprived of their nutrition, die or at least become decalcified. The cartilage which derives its nutrition from the synovial fluid of the joint remains alive, but with the disappearance of the bony nucleus there is nothing to retain the shape of the epiphysis which, therefore, is flattened out under the influence of the body-weight of the patient. Eventually, the vascular supply is restored and new bone is laid down, but not before the epiphysis has become misshapen and deformed. Pending a more exact knowledge of pseudocoxalgia the acceptance of this theory is justified when the results of treatment based on the theory are reviewed.

Clinical Signs: Management.

As noted above, the clinical signs and symptoms, as also the treatment, vary with the stage of the disease.

In *Stage 1* there are few or no clinical signs, and for this reason only a few patients with the early changes of pseudocoxalgia come under observation. There may be a limp, and careful examination will reveal a slight limitation in the range of movement at the joint; the X rays will show the characteristic change in the head of the femur. Various authorities, particularly on the continent, have stated that treatment will not prevent the characteristic cycle of X ray changes. Observation on the effect of treatment in early cases of pseudocoxalgia does not confirm this statement. It is true that even with efficient treatment fragmentation does occur—one cannot diagnose the condition as pseudocoxalgia without; but I am convinced that if the patient is seen early—before the cartilaginous capsule has become flattened and spread out—this flattening can be prevented by the removal of superincumbent body-weight, so much so that when repair has taken place it may be difficult to tell which hip has been affected. It is important to prevent the flattening; the flattening leads to a large expanded head which will not fit into the socket of the acetabulum and the function of the joint is thereby impaired. The relief from weight-bearing should be continued until sufficient bone has been re-formed in the epiphysis to bear the body-weight without danger of the head becoming deformed. If the body-weight is removed the epiphysis does not flatten and the fragmentation of the bony nucleus is not so clearly shown and it is therefore difficult to know when the stage of regeneration has commenced; in view of this uncertainty six months' relief from weight-bearing should be the rule. The surest way of doing this is to confine the patient to bed; but the patient may be allowed up on crutches with a patten on the boot of the sound leg providing the parents can be made to understand that the child must on no account put the foot of the affected leg to the ground. Movement at the hip does no harm. Treatment only aims at preserving the shape of the head of the femur during the stage when it is soft and malleable.

In *Stage 2* the clinical signs are those of irritation of the joint, and may exactly simulate those of an early tuberculous arthritis of the hip-joint—i.e., limp, wasting (usually slight, however), deformity, and limitation of movement in all directions caused by muscular spasm. On the traumatic theory, one may suppose that the signs of irritation are due to the fact that the contour of the flattening expanding head no longer corresponds to the contour of the acetabulum. This stage may be of long or short duration or may even never exist; many cases of pseudocoxalgia do not at any stage reveal their presence clinically. As regards treatment, rest is indicated for as long as the signs of irritation persist. The body is attempting to treat itself on these lines by keeping the joint still by muscular spasm. By rest is meant avoidance of weight-bearing and cessation of movement at the joint. The child should therefore be immobilised on a hip-abduction frame in bed.

Alternately, a plaster-of-Paris spica will enable the child to get about on crutches with a patten on the boot of the good leg to prevent the affected leg touching the ground.

In *Stage 3* the cycle of changes known as pseudocoxalgia are at an end. The active process—whatever it is—has terminated; repair is completed. When, therefore, a patient with pseudocoxalgia is seen in this stage no treatment is called for in respect of the pseudocoxalgia, but the function of a hip-joint that has been altered by the process may be improved. Instead of the normal spherical head of the femur fitting into an exactly similar shaped acetabular socket, the head has an expanded, flattened surface which is markedly different from the contour of the acetabular socket. This incongruity between the shape of the head and the shape of the socket may give rise to two conditions which will impair the function of the joint:—

(1) There may be a limitation of movement preventing normal use of the limb. The important movement that is apt to be restricted is abduction; the leg will not abduct beyond the midpoint (sometimes there is fixed adduction). Now, abduction at the hip is essential for a normal gait. If abduction is impossible, when weight is borne on the affected leg, the pelvis cannot be raised on the opposite side, and to preserve the balance of the body the trunk is thrown over to the affected side, exactly as happens in the gait of a patient with a congenital dislocation of the hip. This "dipping" gait is unsightly and can be overcome by performing a trans-trochanteric osteotomy of the femur and resetting the fractured femur with the lower fragment abducted, as in the treatment of an old tuberculous hip with adduction deformity.

(2) As a result of the asymmetry of the opposed contours of the head of the femur and the acetabulum osteo-arthritic changes occur, causing pain and stiffness and limitation of movement at the joint. The continued irritation, leading to osteo-arthritic changes, can be prevented by an operation at which the head of the femur is exposed and moulded by trimming off its expanded periphery so that it conforms more in size and shape to the acetabular socket. The contour of the head is not changed by this operation, but its size is diminished to such an extent that it will fit into the acetabulum. This does not damage the joint as the remodelled head is covered for the most part with cartilage and fits into an acetabulum lined with normal cartilage.

Summary.

In *Stage 1*, relief from all weight-bearing is required to prevent the softening head from being flattened out by the weight of the body. In *Stage 2*, when signs of irritation are present, rest is indicated—relief from weight-bearing and from movement. In *Stage 3* no treatment is required. In the aftermath of pseudocoxalgia an osteotomy of the femur may be necessary to increase the range of abduction of the limb, or a modified arthroplasty may be desirable to prevent arthritic changes developing in the joint.

George Perkins, M.Ch. Oxf., F.R.C.S. Eng.,
Assistant Surgeon, Royal National Orthopædic Hospital.

Superannuation for Municipal Officers.—The Minister of Health and the Secretary for Scotland have appointed a committee to inquire and report whether any amendments are required in the Local Government and Other Officers Superannuation Act, 1922, and in particular (*a*) whether it is desirable that the scheme of superannuation established by that Act should now be made obligatory on all local authorities; and (*b*) whether that scheme should, with or without modification in respect of particular classes of officers, be made applicable to all persons in the employment of those local authorities, other than school teachers and police. Dr. Drummond Shiels, M.P., is a member of this committee, of which Sir Amherst Selby-Bigge is chairman, and Mr. V. L. Harkness, of the Ministry of Health, secretary.

Special Articles.

THE TUBERCULOSIS CONFERENCE.

LONDON, JULY 6th–7th.

The eleventh annual conference of the National Association for the Prevention of Tuberculosis was held in the Robert Barnes Hall of the Royal Society of Medicine on July 6th and 7th, and reference has already been made to the opening session and to Prof. Pirquet's opening address, read in his absence by Dr. Richard Wagner (Vienna).

Sir William Thompson, Registrar-General to the Irish Free State, submitted a statement showing, for each sex, the tuberculosis mortality under 5 years, 5 and under 10 years, 10 and under 15, and at all ages, in Ireland, per 1000 of the population at these ages, in the years 1911 and 1924.

Year.		Mortality from tuberculosis in Ireland per 1000 population.			
		Under 5 years.	5 and under 10 years.	10 and under 15 years.	All ages.
1911	Males ..	2·09	0·70	0·80	2·14
	Females..	1·96	0·87	1·48	2·09
	Persons ..	2·03	0·79	1·14	2·12
1924	Males ..	1·00	0·45	0·55	1·41
	Females..	0·85	0·44	0·89	1·48
	Persons ..	0·93	0·44	0·72	1·45

Bovine Infection in Children.

Dr. A. Stanley Griffith (Field Laboratories, Cambridge University) detailed the results of the investigations he had made since 1911 on human and bovine infections in children and adults. It had been suggested, he said, on purely theoretical grounds, that small doses of bovine tubercle bacilli in milk might be beneficial to children by conferring on them an immunity to the more dangerous human infection. This hypothesis was based on two assumptions: (1) that the bovine tubercle bacillus was less virulent for man than the human tubercle bacillus; (2) that small doses of bovine tubercle bacilli generally produced mild and curable lesions. But there was evidence that the bovine tubercle bacillus had, if anything, a slightly higher intrinsic virulence for man than the human tubercle bacillus, and that the absorption of a small number of bacilli from the alimentary tract might lead to serious and fatal disease in susceptible infants and children. He had made examinations in the cases of two children, aged 2 and 6 years, who died of tuberculous meningitis; in both instances there were only minimal lesions in the mesenteric glands. Moreover, there was little doubt that the vast majority of the cases of surgical tuberculosis of bovine origin were produced by small doses of tubercle bacilli, since in these cases there was clinically no evidence of disease of the alimentary tract.

It was known that an animal already tuberculous is more resistant to an experimental infection than a normal animal. And it was reasonable to suppose by analogy that a child suffering from a chronic form of tuberculosis, whether of bovine or of human origin, may be more resistant to a subsequent infection. There was, however, not the least evidence that the absorption from the alimentary tract of a small number of bovine tubercle bacilli, which produced no lesions, had a significant or lasting immunising effect.

The numerous instances in children and adults of calcareous and encapsuled lesions which no longer contained living tubercle bacilli could only be taken as evidence of a natural immunity which might or might not have been enhanced by the infection.

Anticipatory De-tuberculisation.

In the afternoon the discussion was opened by Prof. Sir Robert Philip, Vice-Chairman of the Association, who outlined the recent progress of the preventive treatment of tuberculosis in children. One suggestion made was that children born of tuberculous parents should be separated at once from any domestic source of infection, as was successfully practised among cattle. But this method only shelved or delayed the risk. Under present conditions of communal life such a child must run the gauntlet of exposure to infection on subsequent occasions. The same fallacy underlay most attempts to obviate exposure to infection. While in earlier years of infancy it was doubtless sound to delay or minimise exposure, we must be careful not to credit the procedure with undue potential.

A similar fallacy attached to procedure based on the "Grancher" principle, in accordance with which delicate children, sometimes wrongly termed "pre-tuberculous," were transferred from dubious home environment to presumably healthy surroundings in the country. It was frequently suggested, and seemed to be generally believed, that the children were thereby saved from infection. In actual fact, most of the children thus taken in hand were already tuberculised. The excellent results frequently attained were to be attributed to heightening of the child's resistance by maintenance of improved environment—in other words, to a progressive de-tuberculisation along natural lines.

Another proposal was that prior to "spontaneous" infection the child should undergo artificial inoculation (vaccination) in order to anticipate the effect of exposure to infection. Various attempts in this direction had been made. According to Calmette's recent adaptation of the principle, the infant was given by the mouth on the third, fifth, and seventh days after birth a measured quantity of tubercle bacilli, the virulence of which had been reduced by repeated culture on a special medium. It was claimed that a temporary immunity to "spontaneous" infection was thereby attained; the claim was supported by encouraging observations on calves, but it had yet to be seen to what extent, in the absence of illness, parents would consent to submit their newly-born infant to inoculation with tubercle bacilli, however modified, and however simple the process might be. Time and intensive education would be required to leaven popular opinion to the necessary extent.

The plan introduced by the speaker under the name "anticipatory de-tuberculisation" proceeded on the assumption that infection practically always took place during childhood, that the occurrence of the subsequent process of tuberculisation might be definitely determined, and that it was possible to limit and counter tuberculisation by a process of de-tuberculisation.

The process of anticipatory de-tuberculisation had two aspects: (1) Environmental. The influence of improved environment on the resistance of the individual was admitted by all and the principle of the sanatorium should be carried into the whole of social life. (2) Antigenic—by the use (percutaneous) of tuberculin. Antigenic treatment should be commenced when the fact of tuberculisation was definitely established.

The remarkably uniform results observed over many years had much impressed him; not only was the local and immediate result satisfactory, but a systemic influence was exerted which tended to be permanent.

Percutaneous Application of Tuberculin.

Dr. Fergus Hewat (assistant physician, Edinburgh Royal Infirmary) gave an account of the percutaneous application of tuberculin which he had carried on for five years among out-patients from the wards and later at the special tuberculosis clinic. The patients included children with well-marked tuberculous cervical glands on which the surgeon did not advise operation, a number of post-operative cases, and also a considerable number of children who showed a positive tuberculin skin test, slightly enlarged cervical glands, and some degree of muscular wasting, and whose parents stated that they were always tired, that they failed to gain weight, and had poor appetites. In some of these children there were ill-defined abdominal symptoms with attacks of colic at intervals, and palpation showed slight resistance of the abdominal wall towards the right lower quadrant of the abdomen.

If the presence of any local source of septic absorption or any disease other than tuberculosis had been negatived, the children were given a test dose of 10 per cent. Moro's tuberculin ointment made up from Koch's original old tuberculin; this was rubbed into the skin, usually below the clavicle, and if a positive skin reaction was obtained treatment was given once a week, the strength of the ointment being gradually increased as the skin reaction became less pronounced.

No symptoms causing anxiety had occurred during the treatment of these children and very rarely indeed in adults; children were somewhat sleepy the day after the application, and showed a varying degree of skin reaction. Severe reactions amounting to eczema were completely healed in two or three weeks by a simple dressing of olive oil. During the treatment the toxic elements of the clinical picture gradually disappeared; in some two or three months the mothers would say that the children were brighter, more willing to play with other children, and had better appetites. Later the record sheets showed a steady gain in weight, the muscular irritability becoming less, and the children appearing less tired; any abdominal symptoms and physical signs disappeared.

Success was achieved in most cases; failures occurred especially among adults, but the regularity of attendance of the patients was a good index of the benefit they received. In children satisfactory results could be obtained from the use of tuberculin, particularly in a type of patient that drifted in an aimless way from one medical agency to another, never really ill and certainly never fully fit.

Ubiquitous Infection.

Dr. Clive Riviere (Victoria Park Chest Hospital) said that it was generally acknowledged that under present conditions in a civilised community infection with the tubercle bacillus could not be avoided, that such infection was dangerous in early infancy, and that in later childhood a very considerable resistance to tuberculosis was encountered. He laid considerable stress on the importance of immunity; it was mainly due to the general tuberclous infection and the immunity it had given that most of us were able to walk about the tubercle-soaked modern world without any obvious risk.

Prof. Louise McIlroy (Royal Free Hospital) pleaded for better institutional accommodation for pregnant tuberculous women and urged the provision of a special sanatorium with an obstetric staff in London or on the outskirts.

In the evening the annual general meeting of the Association was held in the Robert Barnes Hall. An excellent account was given of the work carried on, including propaganda and the conduct of the Burrow Hill Colony, Frimley, and the Association's new films, the "Invisible Enemy" and "Air and Sun," were shown.

Surgical Tuberculosis.

On the second day the conference was presided over by Sir Robert Philip.

The discussion was opened by Sir Henry Gauvain, who expressed his complete agreement with the views of Dr. Stanley Griffith on the importance of dealing with tuberculous milk, and showed slides illustrating the treatment at Alton and Hayling Island. He thought that personal cleanliness in the house was of more importance than roominess in the prevention of human tuberculosis; a clean pig-sty was safer than a clean palace. A false delicacy sometimes prevented instructions being given to the consumptive as to the necessary precautions. The horizon was widened nowadays; tuberculous arthritis was treated as arthritis in a tuberculous subject and attention no longer concentrated on the local lesion.

No special hospital for the treatment of surgical tuberculosis could be considered complete unless it possessed an out-patient department where discharged patients could periodically be examined, advised, and assisted. On discharge, full, complete, and individual directions should be sent to each parent or guardian. Advice in the choice of occupation and assistance in obtaining suitable employment should be forthcoming as well as medical help. Relapses might occur, deformities might arise, or neglect of simple rules of hygiene might create dangers to be combated and avoided. Facilities were desirable for sending old patients who needed change to open-air camps or holiday homes, particularly those working in conjunction with or under the management of the parent institution. Some cachectic patients, though no longer suffering from active tubercle, urgently required a prolonged stay in residential open-air schools. Others, whose deformities remained in spite of all endeavours to remedy them, should be transferred to a residential technical school for training in a trade suited to their limitations. Without such training restoration to health was insufficient to make them self-supporting, self-respecting citizens.

Prof. J. Fraser (Edinburgh) commented on the very large number of country children with surgical tuberculosis sent into the Edinburgh Children's Hospital, and explained it by quoting the experience of a medical friend who when being shown round a farm noticed a "fevered" cow, obviously heavily infected with tuberculosis, the milk of which was kept for the minister and his family, with the result that Prof. Fraser had to be called in to attend the sufferers. Inspection and supervision of milk were often a dead letter in Scotland; the staff of sanitary inpectors whose duty it was to supervise the production of milk was ridiculously inadequate, and insufficient encouragement was afforded to them in carrying out their duties. The phraseology of the legislation on milk gave him the impression that the wording was arranged to safeguard the producer rather than the consumer. He showed lantern slides illustrating the treatment of surgical tuberculosis at the municipal hospital at Colinton. He thought a word of warning was necessary against the use of mercury-vapour lamps by any except trained workers.

Dr. W. T. Gordon Pugh (C.M.O., Surgical Tuberculosis Service, Metropolitan Asylums Board) gave an account of the work at Carshalton where half the beds are reserved for surgical tuberculosis. He attributed the great improvement obtained nowadays in return of function to improvements in the appliances used and to the fact that a larger proportion of children were now transferred to suitable country hospitals at a comparatively early stage. But he feared that even now some patients were retained in London for weeks, months or even years when they should be in the country. In the first three months of a joint affection even a week's delay in securing constitutional treatment might mean in some cases permanent stiffening instead of complete functional recovery.

The speaker concluded by showing lantern slides illustrating the special spinal and hip frames and carriages used at Carshalton, designed to facilitate the application of heliotherapy. arc-lamp treatment, and gymnastic exercises, while immobilising the diseased part and facilitating locomotion.

General Discussion.

Dr. H. B. Bates (chairman, St. Helens Public Health Committee) initiated a resolution of the conference on the paramount importance of a tubercle-free milk-supply. Councillor Mrs. Dollan (Glasgow) spoke of the lack of courage of those who advocated such half-measures as pasteurisation in dealing with the evil. Prof. Share Jones (Liverpool) wanted full compensation for all tuberculous animals slaughtered for the public benefit. Dr. J. D. C. White (Harrow U.D.C.) elicited from Sir Henry Gauvain an advocacy of the carbon arc lamp for general purposes. Dr. R. M. Fenn (district T.O., West Riding C.C.) mentioned the help the N.S.P.C.C. afforded in obtaining reluctant parents' consent to treatment of their children. Dr. Morgan (T.O., Wallasey) had found that children after their return from institutions lost weight through insufficient hours of sleep, and Dr. A. Brownlee (Glan Ely Tuberculosis Hospital, Welsh National Memorial) called attention to the folly of patients in an advanced stage of phthisis being allowed to return home to infect young children in the family. Dr. W. B. Tomson (Hastings and St. Leonards Tuberculosis Care Committee) mentioned that in Hastings they had utilised the Grancher system: the Brighton Guardianship Society were placing infants in the villages near Hastings.

Sanocrysin Treatment.

The afternoon was given up to the treatment of tuberculosis by sanocrysin. Prof. Holger Mollgaard (Royal Veterinary College, Frederiksberg) said it could not be too strongly emphasised that this treatment was to be considered as a beginning only; clinical experience had already shown that rightly handled it may contribute a great deal to our present possibilities of curing tuberculosis of the lungs. After relating the principal ideas of chemotherapy, founded on the work of Ehrlich and built up on the numerous investigations following in the wake of salvarsan, he went on to develop the essentials of a rational chemotherapy of tuberculosis in which the peculiar features were the resistance of the tubercle bacillus due to its contained fatty substances and the poverty of the tuberculous tissues as regards blood-vessels. Any bactericidal agent to influence tuberculosis must be capable of *penetrating* the fatty system of the tubercle bacillus and be capable of reaching the tubercle bacillus by diffusing from the blood through the tissue at a rate faster than it is decomposed in or excreted from the human or animal body. Up to the present sanocrysin, the sodium salt of auro-thio-sulphuric acid, was the substance which best fulfilled the required conditions; the therapeutic agent was the negatively-charged ion AuS_2O_3.

Extensive animal experiments by Dr. Madsen and himself had established: (1) That sanocrysin is able to produce an acute, very severe intoxication in *highly* tuberculised individuals when injected in doses of 0·5 to 1·5 cg. per kilo. (2) That this intoxication exhibits all the principal features of tuberculin shock and does not occur in healthy animals, even when much larger doses are injected. (3) That the intoxication can be prevented or alternatively cured by means of a specific serum made by immunisation of healthy horses with killed tubercle bacilli. This meant that it was possible to confer upon tuberculous animals or human beings a specific immunity against the lethal effect of sanocrysin, and proved that the substance had a bactericidal influence on the tubercle bacilli in the organism and that the acute intoxication was due to liberated toxins. From the animal experiments they had learnt that the condition of absence of reaction to sanocrysin meant one of three things: (1) Sterilisation until negative results of guinea-pig tests or in Madsen's experiments until negative *result of* the inoculation on Petroff's medium. (2) Total immunity with loss of the Pirquet reaction, but without sterilisation. (3) Simple failure to react because the residual bacilli are too well protected by fibrous tissue or calcareous matter. In these cases the Pirquet reaction persists. In the human subject they had observed the last two conditions. To prove the existence of the first in a hospital clinic would probably be very difficult.

In the animal experiments the transitory stage between the disappearance of the clinical signs of tuberculosis in the lungs and the definite loss of reactions to sanocrysin was marked by "late reactions"—i.e., the reactions appeared two or three days after the sanocrysin injection. This fact was in close accordance with the power of sanocrysin to remain for several days in the blood and to diffuse through animal membranes. In the animal experiments the late reaction had been found only in the last stages of the cure, when the greater proportion of the bacilli had been got rid of. Clinical experience had, however, shown that in tuberculous man late reactions very often occurred at the beginning of the treatment. Such reactions had been found three and even five days after the sanocrysin injection, a fact of great importance because it meant that the injection of a fresh dose within this interval might bring upon the patients the risk of a cumulative effect of the liberated toxins.

The combined sanocrysin-serum treatment had brought about the clinical cure of calves and goats which had been severely artificially infected. Spontaneously infected monkeys, even when in a very serious condition, had been clinically cured, with disappearance of all objective signs of tuberculosis of the lungs, marked decrease of abdominal tumours, and large increase in weight. A year after treatment they were still healthy. The intracutaneous reactions in 12 spontaneously infected calves compared before and after treatment showed that five had lost this reaction and in three cases it had been reduced to the limit recognised in Denmark as representing a cure. In three cases the reaction had remained unaltered and in one case it had grown bigger. As the second tuberculin test was made four months after the treatment, it seemed probable that the loss of reaction was due to a real sterilisation.

Prof. Knud Faber's paper was published in full in THE LANCET of July 11th.

Prof. S. Lyle Cummins, C.B. (University College, South Wales and Monmouth), in a preliminary note said his experience was limited to eight cases, six only of which had been specially selected as likely to respond favourably to sanocrysin treatment. Of the unsuitable cases (the acute pyrexial type with pneumonic symptoms) one had already had five doses of sanocrysin, had suffered very severe reactions and was no better, perhaps rather worse, as a result. Of the other case it was still too early to speak as only two doses had been given, the reactions being very severe. All the selected cases had done well, and the improvement noted in them had been so much more rapid and so much more dramatic than could have been expected in cases of this type that he was unable to avoid the conclusion that sanocrysin was the favourable factor in each of them. His experience led him to think that we should safeguard the use of sanocrysin, not so much by reducing the dosage as by selecting patients with tuberculous lesions of relatively small extent. It would require years of observation and a careful following up of all the cases to decide whether the favourable results so far recorded are permanent.

SIR JOHN MACALISTER MEMORIAL FUND.

A FUND has been opened by the Council of the Royal Society of Medicine to commemorate the 38 years of service of Sir John MacAlister as secretary of the Society. The memorial is to take the form of a portrait to be placed in the Society's house. The list of subscribers to date is as follows:—

Dr. Peter Abercrombie, Dr. James Adam, Prof. J. George Adami, Mr. J. E. Adams, Sir Maurice Abbot Anderson, Dr. W. K. Anderson, Dr. H. Russell Andrews, Mr. Herbert Apperly, Sir Robert Armstrong-Jones.

Dr. Andrew Balfour, Mr. W. Girling Ball, Sir Charles Ballance, Dr. Charles Banks, Dr. G. F. Barham, Lady Barrett, Mr. J. Kingston Barton, Mr. Harold S. Barwell, Dr. F. Clifford Beale, Dr. W. Blair Bell, Sir James Berry, Lady Berry, Sir John Bland-Sutton, Mr. G. F. Harrison Bloom, Dr. Robert A. Bolam, Dr. Elizabeth Bolton, Dr. W. Cecil Bosanquet, Mr. H. Edmund G. Boyle, Dr. Charles R. Box, Mr. G. A. Bradnack, Dr. Edwin Bramwell, Mr. Elmore Brewerton, Sir J. Charlton Briscoe, Mr. W. Rowley Bristow, Dr. George S. Brock, Dr. Alfred Brown, Sir Charles Brown, Dr. J. Mitchell Bruce, Sir Bruce Bruce-Porter, Mr. A. H. Burgess, Dr. Dudley W. Buxton.

Dr. Harry Campbell, Mr. Percival S. Campkin, Dr. J. Walter Carr, Dr. George C. Cathcart, Sir Francis Champneys, Sir R. Havelock Charles, Mr. Arthur H. Cheatle, Sir G. Lenthal Cheatle, Sir W. Watson Cheyne, Mr. C. C. Choyce, Dr. J. F. Christie, Dr. J. B. Christopherson, Sir William Church, Dr. A. J. Clark, Mr. Ernest Clarke, Mr. F. J. Cleminson, Mr. H. S. Clogg, Dr. F. William Cock, Dr. E. A. Cockayne, Mr. Frank Coleman, Mr. Lionel Colledge, Dr. M. A. Collins, Sir Frank Colyer, Dr. Donald E. Core, Mr. Edred M. Corner, Sir Maurice Craig, Mr. Arthur Crook.

Mr. H. Morriston Davies, Mr. E. D. D. Davis, Lord Dawson of Penn, Surg.-Comdr. G. O. M. Dickenson, Mr. Alban Doran, Dr. Ernest Dore, Dr. J. J. Macwhirter Dunbar, Dr. J. Gray Duncanson, Mr. E. Craig Dunlop, Mr. Frederic Durham.

Dr. C. C. Easterbrook, Dr. Wilfrid Edgecombe, Mr. R. C. Elmslie, Dr. A. Geoffrey Evans, Dr. William Ewart.

Mr. C. H. Fagge, Dr. John S. Fairbairn, Mr. H. A. T. Fairbank, Dr. John Fawcett, Dr. Douglas Firth, Dr. Robert A. Fleming, Dr. H. Morley Fletcher, Dr. Ross Ford, Dr. David Forsyth, Dr. R. Fortescue Fox, Mr. Philip Franklin, Mr. J. S. Fraser, Dr. Herbert S. French, Dr. A. R. and Mrs. Friel, Mr. Edward P. Furber.

Dr. W. T. Gardiner, Mr. George E. Gask, Dr. C. Chapman Gibbes, Mr. Harold D. Gillies, Mr. Bryden Glendining, Dr. Lewis G. Glover, Dr. E. E. Glynn, Mr. C. H. Golding-Bird, Dr. W. N. Goldschmidt, Mr. G. Gordon-Taylor, Dr. Albert A. Gray, Dr. A. M. H. Gray, Dr. Emile de Gross.

Mr. Arthur J. Hall, Dr. F. de Havilland Hall, Sir William Hamer, Mr. Frank Harvey, Mr. J. P. Hedley, Mr. G. F. Hentsch, Lt.-Col. H. Herbert, Mr. William Hern, Mr. Harvey Hilliard, Mr. Montague L. Hine, Dr. C. Thurstan Holland, Mr. Eardley Holland, Dr. Geoffrey Holmes, Sir Thomas Horder, Mr. C. H. Hough, Dr. Cecil Hughes, Dr. William Hunter, Dr. Arthur F. Hurst, Dr. Arthur J. Hutchison, Dr. Robert Hutchison.

Dr. W. J. Smith Jerome, Dr. A. Mason Jones, Sir Robert Jones.

Mr. Frank Kidd, Mr. T. Pomfret Kilner, Dr. T. Percy C. Kirkpatrick, Mr. Albert Kisch.

Pugh, Sir James Purves-Stewart.

Miss May Rathbone, Mr. R. Lindsay Rea, Dr. M. B. Reichwald, Dr. George Rice, Mr. Charles F. Rilot, Dr. Clive Riviere, Sir John Robertson, Dr. Alfred R. Roche, Sir Leonard Rogers, Sir Humphry Rolleston, Dr. T. A. Ross, Dr. Amand Routh, Dr. J. S. Risien Russell, Mr. E. Canny Ryall, Dr. John A. Ryle.

Mr. Louis Savatard, Dr. Mary Scharlieb, Mr. C. Schelling, Mr. Sydney Scott, Dr. James Searson, Dr. James H. Sequeira, Sir Seymour J. Sharkey, Dr. H. Batty Shaw, Dr. Edward B. Sherlock, Mr. James Sherren, Dr. W. Knowsley Sibley, Dr. Charles Singer Dr. Harold Sington, Mr. E. G. Slesinger, Dr. Heywood Smith, Mr. J. Priestley Smith, Dr. R. Percy Smith, Mr. Ivan S. Spain, Dr. Herbert R. Spencer, Mr. Walter G. Spencer, Mr. W. T. Holmes Spicer, Dr. E. I. Spriggs, Dr. Graham Steell, Dr. W. Gream Stone, Dr. Florence A. Stoney, Dr. Septimus Sunderland, Dr. W. S. Syme.

Dr. James Taylor, Sir StClair Thomson, Sir John Thomson-Walker, Dr. H. Letheby Tidy, Mr. Herbert Tilley, Sir Nestor Tirard, Dr. J. A. Torrens, Dr. A. Logan Turner, Mr. G. Grey Turner, Dr. William Turner, Dr. W. Aldren Turner, Dr. G. de Bec Turtle.

Mr. George E. Waugh, Dr. Lennox Wainwright, Dr. Jane Walker, Mr. F. Ashton Warner, Dr. W. M. Crawford Watson, Dr. Patrick Watson-Williams, Mr. A. E. Webb-Johnson, Mr. E. F. White, Dr. J. Douglas C. White, Mr. R. H. Anglin Whitelocke, Dr. T. Stacey Wilson, Dr. Thomas Wilson, Dr. T. Outterson Wood, Dr. A. Stanley Woodwark, Dr. H. W. Wunderly, Dr. F. Wyatt-Smith, Dr. Andrew Wylie, Dr. Andrew Ellis Wynter.

The total received to date is £615. The list is still open and subscriptions should be forwarded to the hon. treasurers, Royal Society of Medicine, 1, Wimpole-street, London, W. 1.

NATIONAL HEALTH INSURANCE AND THE MEDICAL SERVICES IN THE IRISH FREE STATE.

(FROM OUR DUBLIN CORRESPONDENT.)

A VOLUME of appendices to the Interim Report of the Committee of Inquiry on National Health Insurance and the Medical Services was issued last week. It contains the various memoranda submitted to the Committee, together with a summary of the evidence given by the witnesses. Nowhere in the evidence is there any opposition to the establishment of a national medical service for the Free State.

The strongest case in its favour was made by Dr. J. Power of the Irish Medical Committee, who received strong support from unexpected quarters. Mr. R. J. P. Mortished, speaking on behalf of the Irish Labour Party, found that a State Medical Service would be very desirable. The General Council of County Councils took the same view definitely in the following opinion :—

> "We recommend the establishment of a State Medical Service paid by the State and appointed under arrangements made by the State Health Authority. If it should be found impracticable to establish this service immediately, the promised legislation should make provision for its establishment as soon as possible, and the health scheme should be drafted with a view to its eventual establishment."

As some misunderstanding appears to have arisen as to the precise meaning of this recommendation, the General Council of County Councils was asked to submit a supplementary statement. The secretary of the Council then wrote as follows in regard to his evidence :—

> "During the course of my evidence the chairman suggested that the General Council should consider the relative merits of the making of appointments under a State Medical Service, (*a*) by the central health authority, or (*b*) by the local health authority from a panel submitted by the central authority. I have consulted the Executive Committee of the General Council on the subject, and am directed to state that, in their opinion, appointments to a State Medical Service should be made by the central health authority on the results of competitive tests—practical, as far as possible. They are of opinion, further, that in the conditions of appointment to a State Medical Service provision should be made for periodical tests of continued professional fitness."

The importance of the advocacy of a State Medical Service by the representative body of the county councils lies in the proof of willingness of these bodies to rid themselves of a patronage they possess at present. Equally important with the support of the county councils is that given by the Department of Local Government and Public Health. A memorandum submitted by the Department in reference to recent administrative changes in regard to medical treatment of the poor says that the Minister, in the changes he has so far made, has kept in view the possibility of a State Medical Service being introduced at a later date, and has been careful to say nothing that might militate against its being set up.

RADIUM AT THE NEW TORBAY HOSPITAL.—Miss V. E. Wills has given £6300 towards this hospital. Of the total such sum between £2000 and £4000 as may be necessary is to be used for the purchase of radium, and a further £500 is allocated for the construction and equipment of a radium room.

PROCESSIONS AND BALLOTS FOR HOSPITALS.—The authorities of the Church of Holy Trinity, Sloane-square, London, have protested to the Council of the Metropolitan Hospital Sunday Fund against the practice of holding Sunday processions of "men, women, and children dressed in weird and often vulgar costumes, the processions being the pretext for a lot of shouting and shaking of money-boxes," and of "appealing to the gambling spirit in issuing handbills on 'how to win a fortune for half-a-crown.'" It was pointed out that these processions are organised by an independent committee which gives the proceeds to the hospitals of its choice, but not necessarily to one hospital. The subject of "ballot appeals" was referred to the General Purposes Committee with instructions to report to the Council.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the statistics for 1924 of a group of two county boroughs, one city, and four boroughs :—

Name of borough.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Croydon C.B. ..	196,000	17·6	11·6	0·96	1·5	2·3	29	56	2·9
Eastbourne C.B.	54,830	12·1	10·9	0·79	1·5	1·6	40	58	—
Swindon B. ..	56,570	17·1	10·8	0·94	1·4	2·4	32	63	1·0
Worcester C. ..	50,220	17·2	13·3	0·97	1·2	2·9	22	51	1·1
Colchester B. ..	43,940	16·9	11·3	0·86	1·4	3·0	—	45	0·0
Hyde B.	33,770	14·7	14·0	1·10	1·6	2·7	40	103	4·0
Yeovil B.	16,060	17·6	10·8	0·87	1·3	1·6	42	78	3·5

C.B. = County Borough. C. = City. B. = Borough.
— = information not available from report.

Croydon.

Dr. H. P. Newsholme's report on the public health and school medical service marks an advance all along the line. Unification of the medical and nursing services has been achieved. Each health visitor is now responsible for all forms of health-visiting and school-nursing in her district. The school medical officers are also medical officers to the infant welfare centres, and each one is made responsible for the supervision of the health of the children attending a particular group of schools.

Negotiations have been completed for the extension of Cheam Sanatorium from 50 to 85 beds. There will then be 40 beds for tuberculous patients from Croydon, 40 for Surrey, and 5 for Kent. Early in 1925 the council approved a scheme for the development of occupational work at Cheam. The maternity hospital, St. Mary's Hostel (17 beds), is conducted by the Croydon Mothers' and Infants' Welfare Association, which is subsidised by the council. An additional subsidy for the purpose of extending the hospital and providing 13 additional beds is to be paid, and the council have approved proposals for the erection on a site adjoining the hostel of a new building at a cost of £6330. The new building will provide accommodation on the ground floor for an infant welfare centre and antenatal school, massage, dental and eye clinics, while the first floor will provide a sick nursery of 12 beds, one isolation cubicle, a ward of two beds for nursing mothers, and quarters for the resident staff.

Tuberculosis care work is to be handed over to the Croydon Council of Social Service, a voluntary organisation which coördinates many social activities, and includes representatives of official bodies. The council will provide an organiser trained in social work to assist the tuberculosis officer and the Council of Social Service. An occupation centre for the mentally defective has been established and is giving good results. Another new departure is an arrangement with the governors of the Croydon General Hospital for a public laboratory on an extended scale. Formerly the corporation bacteriological work was carried out at the hospital for infectious diseases. Under the new arrangement the Croydon General Hospital will provide a suitable building for the laboratory. The pathologist will be a salaried officer of the corporation and an honorary officer of the hospital, and will carry out all the pathological and bacteriological work required by the corporation and the hospital. The new arrangement is welcomed by the medical practitioners of the town. Early in 1925 arrangements were approved for the home nursing of measles, whooping cough, ophthalmia neonatorum, puerperal fever, epidemic diarrhœa, and infantile paralysis by the Croydon Nursing Service at a fixed charge to the corporation of 1s. 4d. per visit for such cases as are referred by the medical officer of health.

The school report concludes with an interesting inquiry into the incidence of adenoids, which is worthy of separate consideration. Adenoids are undoubtedly an important factor in diminishing a child's educational capacity.

Eastbourne.

Dr. W. G. Willoughby reports that the rainfall was 32·73 inches, being about 2 inches above the average for the last 40 years. The sunshine record was 1778·1 hours, which is claimed to be the fourth highest in the United Kingdom, and is 22·5 hours less than the average of the last 37 years. A "peculiar recrudescence" of enteric fever occurred during the year. There were ten cases from January to October, and in all those tested the blood-cultures showed paratyphoid B. No cause could be found, and all the patients recovered. The new male cases at the venereal diseases centre increased from 50 to 58, and the new female cases from 34 to 47. The increase is thought to be due to greater appreciation of the clinic. The existing cases of tuberculosis are being steadily reduced, especially of bone and joint tuberculosis; the deaths from tuberculosis in 1924 numbered 44, compared with an average of 51·7 for the previous ten years. The want of suitable occupation for cases leaving the sanatoria is badly felt, and Eastbourne is no exception as regards imperfection of after-care schemes.

A striking feature of the infant mortality was the large number of deaths during the first weeks of life; thus of 39 infant deaths 27 occurred in the first month One hundred and forty-three confinements took place at the municipal maternity home. Two of the babies were stillborn, and 18 died within ten days of birth. The infant mortality-rate for the first fortnight after birth in the home was 55 *per* 1000 births. One hundred and forty-four babies were born in the Infants' Home at 9, Upperton-road. Of these six were stillborn, six died on the first day, and two on the eleventh day. Antenatal work is growing, and 203 expectant mothers sought advice at the two antenatal clinics, a high proportion, seeing that the total births numbered 606. Insufficient housing and unemployment, says Dr. Willoughby, are the most serious adverse factors with which the department has to contend. Allowing six persons per house, about 150 houses are required annually to meet the increase of population. During the six years since the war only 405 houses have been completed. A better supply of small houses is needed. "The outlook for 1925 and 1926 is better and houses costing below £600 may be erected."

Swindon.

Dr. Dunstan Brewer again voices the urgent need for an adequate hospital unit in Swindon. During the past year progress has been made in the sanitary conditions of the district. The sewage works at Rodbourne have been completely reconstructed. The storm-water scheme for the newer part of the town was successfully completed during 1924, and despite the wetness of the year no flooding occurred in the lower part of the town. During 1925 it is hoped to reorganise the collection of house refuse by the provision of sanitary dustbins, and to make progress with the reconstruction of public lavatories. The canal is now practically filled up, thus removing an old-standing nuisance. The housing shortage does not diminish, though 200 new houses were erected in the borough during the year. "The position of the larger families becomes relatively and actually worse with each succeeding year." The corporation housing scheme is entirely without the borough. Dr. Brewer believes that it is possible to control scarlet fever, and founds his belief on the theory that scarlet fever is only infectious for the first day or two, but that certain persons possess the capacity of remaining infective for unlimited periods. It is by the control of these few infectors that he hopes for results. Diphtheria ceased to be endemic in Swindon in 1921. During 1924 60 cases of this disease were notified, but for the first year in its history no deaths from this disease occurred in the borough. For the better control of acute infectious diseases of the nervous system Dr. Brewer would like to have all forms of meningitis notified. The report contains an interesting appendix on the maternity and child welfare scheme of the borough with suggestions for its future development. The chief expenditure suggested is on a new maternity and infant hospital built on the pavilion system on an adequate acreage, and making provision for diseases of pregnancy, normal delivery, abnormal delivery, the puerperal state, and non-infectious diseases of infants.

Worcester.

Dr. Mabyn Read records that at the beginning of June, owing to the rapid rise of the Severn, 359 low-lying houses were flooded, and that active steps were taken by the health committee to relieve the consequent distress and to cleanse and disinfect the houses after the flood had subsided. The General Infirmary established during 1923 a fully equipped orthopædic department under the charge of Mr. Norman Duggan, F.R.C.S. In May, 1924, the council appointed Mr. Duggan honorary orthopædic surgeon to their Newtown hospital for the treatment of bone and joint tuberculosis. A satisfactory scheme has thus been provided for the treatment of these patients. In the first place they attend the orthopædic clinic at the General Infirmary, where they receive in-patient treatment, if necessary, and are provided with proper appliances. They then continue their treatment in the open-air wards of the corporation Newtown hospital. It is hoped soon to provide artificial-light treatment as part of the scheme.

Colchester.

Dr. W. F. Corfield reports an increase in respiratory diseases probably due to the wet and cold year, but that the pulmonary tuberculosis death-rate is lower than it has been for many years. Five members of the staff at the isolation hospital contracted scarlet fever. All of them made a good recovery. On the other hand, no cases of diphtheria occurred among the staff, and this result may have been due to the fact that all the junior staff who gave a positive Schick reaction were immunised. There was a decided increase in scarlet fever in the borough; 183 notifications, with five deaths. Two of the fatal cases were imbeciles from the Eastern Counties Institution, and Dr. Corfield points out the low resistance of such children to infections and to a fatal ending. There was a widespread epidemic of measles, with only two deaths, and Dr. Corfield attributes this result to the fact that parents have been educated by the health nurses to regard measles as a serious complaint. Whooping-cough, on the other hand, he says, is not treated seriously enough.

Hyde.

Dr. Nicolas Gebbie refers to the prevalence of pneumonia and respiratory infections and to the removal of the smoke cloud as the most important preventive measure. It will be noticed that Hyde is exceptional in having a three-figure infant mortality-rate, but a chart in the report shows that, whereas the infant mortality was just under 200 for the first five years of the century, it has been just under 100 during the last five years. The new maternity and child welfare centre, opened in June, is a valuable asset, says Dr. Gebbie, "and as a war memorial pays a worthy tribute to the men of Hyde who fell in the

Great War." Photographs and a plan of the building are included in the report. "The present rate of supply of houses in the borough is totally inadequate to meet present needs." Of 25 samples of milk examined for tubercle bacilli, three were found to be infected. In his school report Dr. Gebbie says there is a marked improvement in the general standard of cleanliness, but that inspections at frequent intervals are absolutely necessary to maintain the improvement. In July a committee of teachers arranged a visit to Wembley, and 353 children had to be examined by the medical officer; 51 per cent. of these showed evidence of successful vaccination. A few certificates were withheld on account of "nits" in the hair. The prospect of missing the trip and the energy of the school nurses in using Sacker combs at the clinic produced the desired result, and the withheld certificates were eventually granted.

Yeovil.

Dr. Charles W. Gee reports that the housing shortage still continues, and that a large number of houses are occupied by two or more families. The school care committee continues to provide from voluntary contributions much appreciated assistance to necessitous children who do not come within the scope of the Poor-law. Dr. Gee says an open-air school is badly needed to deal with pre-tuberculous anæmic and debilitated children, and special classes in such a school for dull and backward children. "In the meantime playground classes should be utilised as much as possible."

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 25TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 65; scarlet fever, 1580; diphtheria, 808; enteric fever, 60; pneumonia, 606; puerperal fever, 44; cerebro-spinal fever, 4; acute poliomyelitis, 0; acute polio-encephalitis, 2; encephalitis lethargica, 50; continued fever, 4; dysentery, 5; ophthalmia neonatorum, 107. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, 44 from measles, 8 from scarlet fever, 30 from whooping-cough, 22 from influenza, and 29 from diphtheria. There were 61 deaths of children under 2 years from diarrhœa and enteritis, as compared with 50, 44, and 29 in the preceding weeks. In London itself there were 9 deaths from diphtheria, 6 from whooping-cough, and none from influenza.

SURGERY BEFORE LISTER.

To the Editor of THE LANCET.

SIR,—In your review of Sir William Watson Cheyne's "Lister and His Achievement," being the first Lister Memorial Lecture delivered at the Royal College of Surgeons of England on May 14th, you say: "There is no reader of our pages but knows what surgery was before Lister's time. . . ." This, I think, is questionable, and the difficulty is to enable the present generation to realise the state of affairs that existed at that period. Even those who experienced something of the fringe of its horrors are apt sometimes to forget the advantages we enjoy to-day and to neglect some necessary precaution, with the result that we are pulled up suddenly only to realise their importance by a calamity. Well do I remember my first visits to a surgical ward in one of the smaller hospitals nearly 35 years ago, where the newer methods of wound treatment had not yet taken root. The surgeon pulling on the silk ligatures which had to be left hanging from the end of an amputation stump was a familiar sight and the regular application of linseed meal poultices to a suppurating tuberculous hip with its sour, sickly-smelling discharge. The earlier stage of a similar case left a still more vivid impression, for I can still see the surgeon incising a tuberculous abscess without any precautions whatever—for he neither removed his coat nor bathed his hands—and inviting me out of the kindness of his heart, for he was a great teacher, to thrust my unwashed finger into the freshly opened abscess so that I might feel the eroded head of the femur!

I have been told that in the old Royal Infirmary at Newcastle there was a "condemned" ward into which post-operative cases were put after a first rigor which so frequently ushered in a fatal septicæmia, and that patients commonly died of septicæmia after such simple operations as amputation of the toe, and that severe sepsis after any operation meant many months of painful suffering often followed by permanently impaired health. As Osler said, only those who have lived in the pre-Listerian days can appreciate the revolution which has taken place in surgery. All students ought to read the story of "Rab and His Friends," by Dr. John Brown.[1] There they will find in beautiful language an accurate description of an old-time operation for removal of the breast with the most wonderful picture of the after progress cruelly marred by the onset of a fatal blood poisoning—a name more embracing and expressive than those now commonly used. I can also strongly recommend "The Edinburgh School of Surgery Before Lister," by Alexander Miles, published by A. and C. Black. From it they will gather a vivid picture of operations in the earlier days and of the great men bold enough to perform them. But there is still room for some work describing the state of wound treatment just before Lister, and it should be done now while those who can most vividly write the story are still with us.

Of course, mention is often made of the conditions existing before Lister, but we require an exact description with some detail as much for educational as for historical purposes. I may be ignorant of what already exists, but the sort of work I have in mind should be easily accessible and suitable for student reading. It would supply a real want.

I am, Sir, yours faithfully,
Newcastle-upon-Tyne, July 31st. G. GREY TURNER.

THE ÆTIOLOGY OF CANCER.

To the Editor of THE LANCET.

SIR,—I think it ought not to be forgotten that ten years ago[1] Dr. A. S. Leyton and Dr. Helen G. Leyton isolated a streptothrix from sarcomata in rats and reproduced the disease in normal rats. Their procedure was briefly as follows: The press-juice from the tumour was passed through a porcelain filter, cultures were made from the filtrate, and the streptothrix grew. Rats were inoculated with the streptothrix and sarcomata reproduced. Acting on this brilliant piece of work Mr. W. Stevenson and I were able last year to cure a large sarcoma in a woman aged 38. The tumour was situated on the left side of the neck, and was so large that the patient's neck was turned to the right and fixed. Mr. Stevenson had reduced the tumour by about one-third of its bulk by radium. I then removed an intact piece of the tumour and obtained a profuse growth of diphtheroid bacilli (streptothrix). An antigen of this produced marked focal reaction in the tumour and general reaction. The tumour steadily retrogressed with the course of inoculations and completely disappeared. Some months later there was a recurrence in the glands of the left armpit from which I isolated the streptothrix again.

I am, Sir, yours faithfully,
University College, Dublin, July 24th. W. M. CROFTON.

To the Editor of THE LANCET.

SIR,—In your leading article of July 25th on the above subject you state "imagination can run on almost indefinitely and in this case legitimately." With that before me, I venture to add to the flood of hypotheses with the hope that my addition thereto may not be regarded as illegitimately indefinite. I use, or it may be unwittingly pervert, the facts summarised in the Ministry of Health Memorandum (July, 1924) by Dr. J. A. Murray, by Dr. Mervyn Crofton in a paper[1] on Cancer, and the published work of Dr. A. Leitch.

[1] THE LANCET, 1916, i., 513.

There is no specific germ of cancer. The government of metabolism at sites in the animal body presumably varies in perfection, in accord with the grade of strain to which these are subjected in fulfilment of the respective functions subserved. Local irritation of mechanical, chemical, and toxic origin may be followed at certain sites by interruption of the sequence of processes of maintenance. In the human being more especially this may occur when these factors are aggravated by senescence and faulty dietetics. Independent of phagocytosis in the blood-stream, cell growth may be aided by ultra-microscopic microbes acting direct on effete matters, their influence on which may be restricted by toxic substances possessed by the healthy cell. In the presence of submaximal injury of cells as contrasted with their actual death, a struggle would ensue; in this the scavenger microbe may be at a disadvantage, toxic substances may gain the upper hand. When the process of irritation is chronic, the cells thus guarded would depend largely on physico-chemical processes (as illustrated in vitro experiments with fresh culture medium), and would assume a practically independent and insular existence with a scavenger service reduced to a minimum, if at all existent. Cells rich in toxin would guard the periphery. The toxic substance having fulfilled the function of protection locally might become surplus to requirements (*as shown in* the experiment in vitro of lack of growth in absence of fresh culture medium) and on entering the circulation would interfere with the scavenger microbe at the particular sites liable to overstrain in functioning, or owing to local irritation as defined above. Hence, there is *no specific metastasis*. On such an hypothesis cure of cancer would depend upon the judicious and intermittent flooding of the independent cell area (strictly within its confines) with the ultra-microscopic scavengers, in the endeavour to restore the balance of normal growth.

It seems to me that Dr. Gye's conclusion *that two* factors are necessary is met by this hypothesis, and is strengthened by the statement in the memorandum of the Ministry of Health that "the *active agent* behaves thus far like an ultra-microscopic virus, *but it has not yet been possible to produce the disease with artificial cultures of it.*" (Italics not in the *original.*) You seem to approach the subject much from the same point of view I express when, in your *leading* article, you state, "It may turn out that the virus does not normally exist in the body at all, but is generated within it in something of the same *relation* to the cells as the bacteriophage has to the bacilli."

A further tendency in this direction is found in your mention of the doctrine of Drs. Gye and Cramer involving "defence rupture" (kataphylaxis). My hypothesis would, however, regard Dr. Gye's "particulate bodies" as scavengers whose presence under normal conditions stimulates the production of a defence toxin in proportion to the zeal permissible on their part. When Dr. Gye injects both the particulate body (his "virus") together with the toxin (his "specific factor") he imitates, presumably, in healthy tissue the circumstance of the struggle of the scavengers and the defence toxin in the metabolism incident to submaximal cell injury; and is successful in securing the results he desires, because from the start he handicaps the particulate bodies by upsetting the balance with toxin in excess to the normal of the site. In this view it would be premature to regard the particulate body as a virus. Having regard to the largely accepted local irritation theory in causation of cancer, more light would be thrown on the subject were Dr. Gye's "virus" to be injected without his "specific factor" in tissue which recently has been subjected to submaximal injury.

This hypothesis may be *pour rire* when examined by experts: but I trust it will be regarded as quite as good as that which was accepted some time back as to the baneful effects of tomatoes in producing cancer!—I am, Sir, yours faithfully,

W. G. KING,
Colonel, I.M.S. (Ret.)

Hendon, N.W., August 3rd, 1925.

To the Editor of THE LANCET.

SIR,—Dr. Gye's remarkable researches have aroused intense interest. They have a special interest to me through my association with the work, on lines very similar in theory, of my father, the late Dr. W. Ford Robertson. His paper[1] on the Relation of Carcinoma to Infections describes the result of inoculation of mice with cultures of an anaerobic diphtheroid bacillus isolated from five different human breast carcinoma and one rodent ulcer. He did not filter these cultures as he looked upon this bacterium, universally present under these conditions, as being probably the essential factor. Nineteen out of the 22 experimental mice were inoculated with pure anaerobic diphtheroid cultures in saline which had been subcultured from the primary broth into special anaerobic hæmoglobin glucose agar for the purpose of enhancing purity of culture. On the two remaining mice primary cultures were used. In the light of Dr. Gye's work it would appear that Dr. Robertson deprived the inoculum of some of its virulence, for of the six positive experiments in the group, the resulting tumours did not appear until a lapse of from 9 to 23 months, while in the two cases where primary cultures were used (presumably containing besides the anaerobic diphtheroid bacillus a filterable virus) the period for tumour development was as short as two to three months.

Dr. Robertson's experiments are remarkable, in that out of a total of 22 mice which were inoculated with human cancer anaerobic diphtheroid cultures, without any specific substance, eight developed carcinomata and one sarcoma, and a further nine developed hyperplastic tumours strongly suspicious of malignancy (18 of these being examined and verified by the Laboratory of the College of Physicians, Edinburgh), making a total experimental production of 36 per cent. tumours of definite malignancy, and a further 41 per cent. of suspicious malignancy.. Control mice to the number of over 30 were kept for longer periods during the experiments without developing any kind of tumour.

With regard to the specific substance this must have largely been removed by the technique adopted in the majority of Dr. Robertson's experiments, and further, only two mice were inoculated with cultures that might contain specific substance, the others being treated with pure surface subculture in saline, which presumably could not have contained this material. Tumours were produced, however, but in a relatively much longer period, suggesting that owing to the removal of specific substance or its destruction by secondary organisms, further time was required for its redevelopment in vivo, either by unknown toxic factors, the diphtheroid itself, or the virus incorporated with it.

I am, Sir, yours faithfully,
W. MARSDEN FORD ROBERTSON.

Southport, July 28th, 1925.

To the Editor of THE LANCET.

SIR,—There are probably few pathologists in this country who have not already read the most interesting papers on cancer and the ultra-microscopic viruses by Dr. Gye and Mr. Barnard. The work, moreover, has been widely discussed and the results and conclusions appear to be accepted as correct by many pathologists. All, however, who wish well for the reputation of British medical science will be anxious lest an over-enthusiastic reception should blind workers to any possible sources of error which a more considered judgment might suggest ought to be thoroughly probed before a work of this nature is accepted as having been *proved* to be correct. Nothing could do greater harm to the reputation of British scientists that they should be shown to be in error, possibly in a year's time, by some worker in a foreign laboratory. I feel sure, therefore, that both Dr. Gye and Mr. Barnard will appreciate the desire of some workers to be given a little more information on several crucial points, a satisfactory answer to which would go a long way towards convincing those whose critical analysis of the results leaves them in some little doubt.

---

[1] The Bordeaux Congress, 1924.

[1] Brit. Med. Jour., 1921, ii., 929.

In view of the fact that ultra-microscopic viruses will tolerate pure glycerine and to a certain extent ether, is Dr. Gye convinced that his chloroform-treated filtrate is quite free from the virus or contagion? Might not a small amount of specific contagion be left and be made active by non-specific products, including acids present in what he believes to be his cultures, in the same way that toxins affect the virulence of bacteria? Can he give us some experiments conclusively disproving this possibility? How many times has the experiment given in Chart 5 been made, and has the result always been the same? Have large quantities of the same treated filtrate only been inoculated, as controls, with negative results? Have cultures of non-cancerous tissue been tested side by side with cultures of cancerous tissue when the same treated filtrate was added in each case? In making subcultures from the primary cultures have any comparative experiments been carried out with subcultures made after heating the *primary* culture to such a temperature that any virus would certainly be destroyed? Would a fifth subculture from this fail to be made active by a chloroform-treated filtrate which for certain made active the fifth subculture derived from the unheated primary culture? Such experiments giving clean-cut results would, I suggest, be considered weighty evidence by most pathologists who may not be quite convinced by the result given in Chart 11.

This investigation of Dr. Gye and Mr. Barnard must have a considerable effect on all investigations at present being carried out on the ultra-microscopic viruses, and it is of great importance to other workers that their own investigations shall be carried along the right lines. I am sure if Dr. Gye is in a position to give us the information I have suggested it will be of great assistance to, and will be appreciated by, those working in other laboratories.

I am, Sir, yours faithfully,
F. W. TWORT.

The Brown Institution, University of London,
July 20th, 1925.

To the Editor of THE LANCET.

SIR,—Dr. Gye's paper in your issue of July 18th, in which he reports the very important results of his experiments on the passage of the Rous chicken sarcoma No. 1, raises a point of interest which has been in my mind since I first knew of his preliminary work, and which acquires more importance in the light of his more recent results with mammalian tumours. The point concerns the second filterable fowl tumour referred to in his paper—chicken sarcoma No. 7, of the Rockefeller Institute—a tumour which I originally transplanted and passed by filtrates, and the details of which were first published—without my consent—under the names of Rous, Murphy, and Tytler.[1] This tumour I have described separately.[2]

The original of this tumour was an apparently inert, cartilaginous nodule on the keel of the sternum, and during the first few passages the growth remained entirely benign in type—well encapsulated, cartilaginous during the first few weeks of growth, ceasing to grow after six to eight weeks, and then becoming more or less completely ossified, with the production of marrow spaces and blood-forming tissue. At about the fifth or sixth passage, however, it quite rapidly began to take on malignant qualities, and in the course of three or four passages became transformed into a soft, rapidly growing and invading, undifferentiated tumour, and at this stage I was able to pass it by means of a Berkefeld filtrate. The tumour passed out of my hands at this time, and for information as to its later course I was indebted to my former colleague, Dr. J. B. Murphy, from whom I understood that it acquired most of the characteristics of chicken sarcoma No. 1, to which it now bore a striking resemblance histologically, but always retained certain specific qualities of its own.

The point I wish to make, in the light of Dr. Gye's work, is the possibility that this originally benign tumour may have become infected by the active virus of chicken sarcoma No. 1. Numerous fowls bearing the latter tumour—many with large, extensively ulcerated growths—were being handled in the same laboratory, the danger of contagion was not at that time seriously considered, and we did not have the conception of a virus which could outlive the activity of the tissue preparations in use.

The suggestion is entirely speculative and impossible of confirmation, and would, indeed, have a very limited interest in connexion with the fowl tumour alone. But Dr. Gye's work leads us to hope, as I understand, with some justification, that he will be able to demonstrate the activity of his virus in the production of mammalian tumours, and to extend the results of his work to the whole field of malignant growths. In this case, the point I have raised may perhaps supplement in a small way the suggestion contained in his epoch-making work that contagion in cancer may be a factor of importance, a view which will no doubt appear revolutionary to the medical profession as a whole, as it does to me.

I am, Sir, yours faithfully,
W. H. TYTLER.

King Edward VII. Welsh National Memorial
Association, Central Tuberculosis Laboratory,
Cardiff, July 20th, 1925.

To the Editor of THE LANCET.

SIR,—It is a great pity that your leading article of July 25th did not appear in the same issue as Dr. Gye's communication. The communication was accompanied instead by a leading article which took a purely one-sided view of the question, accepting Dr. Gye's hypothesis as well as his facts, and even going beyond them in suggesting that the "specific factor" may be produced from irritated tissues, whereas Dr. Gye had produced it only from pre-existing tumours. Your article of July 25th took a more judicial attitude, and suggested that there might be another explanation of Dr. Gye's facts than his hypothesis of an extrinsic parasite, but, as far as I have seen, no notice of this second leading article has been taken by the daily press. The impression has thus been transmitted throughout the world that Dr. Gye has discovered the cancer parasite, and this impression is intensified by the unqualified support of the leading medical journal in the kingdom.

Pathologists are apt to ignore, or to regard with contempt, the views as to the constitution of living matter which are accepted by biologists. These views are that the cell is not the ultimate unit of life but is itself composed of different orders of smaller living units each of which is capable of growth and multiplication. Some of these units such as chromosomes, centrosomes, Golgi bodies, chondriosomes, &c., are visible under the microscope and their growth and multiplication can be studied directly. Others are invisible, but their existence is supported by very strong evidence.

According to Weismann the ultra-microscopic particles (determinants and biophores) are specific in character and determine the nature of the cells of which they form part. Since these views were first promulgated they have received remarkable independent confirmation in the facts of Mendelian heredity. There is little or no difference between Weismann's "determinant" and Mendel's "factor." Both are intercellular and ultra-microscopic, and capable of growth and multiplication. The "determinant" determines the nature of the cell and the "factor" determines the character with which it is associated. It appears to me that here we have an explanation which is in better accord with Dr. Gye's facts than his own hypothesis of an extrinsic cancer "virus."

---

[1] Jour. Amer. Med. Assoc., 1912, lix., 1793.

[2] Jour. Exp. Med., 1913, xvii., 466.

Since cells can be cultivated under artificial conditions apart from the organisms of which they form part, there is no a priori reason why it should not be possible to cultivate these ultra-microscopic units apart from the cells. It appears to me that Dr. Gye's facts would be explained equally well on this supposition as they would be on his supposition that the "virus" is an extrinsic agent; and, for some of his facts, my suggestion offers the easier explanation. Cancer cells presumably contain an ultra-microscopic "factor" or "determinant" for cancer, and it is quite possible that Dr. Gye has succeeded in cultivating this factor, since he has not brought forward any evidence that his "virus" is an extrinsic germ.

The great majority of pathologists have always recognised that the known phenomena of cancer are incompatible with the theory of an extrinsic specific causal agent, and it does not appear that Dr. Gye's facts have removed the objections to this theory. To take one point only, it is now possible to induce cancer in animals without taking thought of any parasite. If an extrinsic parasite is to be considered necessary for the production of cancer, this organism must be present at all times either in all animals or else in the atmosphere. Otherwise it would be impossible to produce cancer without the specific introduction of the cancer parasite. There is, thus, very strong evidence in favour of the view that this so-called "virus" is not an extrinsic parasite, but is a constituent part of the cancer cell itself. This view is in accordance with the phenomena of cancer, whereas the hypothesis of an extrinsic agent is not. The question whether the virus is extrinsic in origin or is derived from the cancer cell itself is one of extreme importance, and it is much to be regretted that Dr. Gye's article was not submitted to more adequate criticism before being published, so that both sides of the question could have been presented to the public at the same time.

If my suggestion is correct, this work of Dr. Gye opens up vast possibilities in the way of cultivating Mendelian factors in vitro.

I am, Sir, yours faithfully,

CHARLES POWELL WHITE.

Manchester University, August 3rd, 1925.

To the Editor of THE LANCET.

SIR,—Dr. Gye's recent investigations have been of special interest to me, because I believe his virus will prove to be identical with the ultra-microscopic phase of the complex micro-organism which I described in 1921. This micro-organism I have obtained from a large number of cancers of all types. I have shown that the larger elements (coccal, bacillary, fungal) which soon appear in any ordinary culture medium containing a piece of cancerous tissue can be traced directly from minute elements, which emerge from the cells, or indirectly from an amorphous material, which escapes from the cells as globules and rods and which in this early stage is often curiously resistant to ordinary stains. This unstained "plasm" often first appears in and escaping from the dying cells as minute elements just on the verge of visibility. A study of these facts led me to write in 1922 that "the organism has, during its parasitic phase, acquired the faculty of infecting individual cells and of living in a sort of symbiotic relationship with the cells which it inhabits. This conclusion . . . goes far to confirm the view which I advanced in a previous paper (1921) that the organism lives parasitically in a minute phase which is unrevealed by ordinary methods of staining." The globules and rods can sometimes be seen to emerge from the cells with a clearness that is diagrammatic. The organised forms (coccus, bacillus, yeast) often spring from refractile elements, which appear in and are detached from the globule and rod. Glover of New York and his colleagues have recently described a microbe which they have obtained from all types of cancer and whose general characters are similar to mine.

A remarkable feature of this micro-organism is that the alternative forms, although springing from one common stock, can pursue each an individual and stable life as coccus, bacillus, or yeast, and they may resist any efforts to change them, although I have frequently during five years' study convinced myself that under certain conditions any one form can pass over into any other form. These facts are foreign to ordinary bacteriological teaching and have made my views uncongenial to many bacteriologists, although there is a great deal of evidence in the literature to support them (Löhnis, Mellon, de Negri, Hort, Almquist, &c.). It is, I believe, apparent from the recent literature that fixity of form in bacteria is illusory as a criterion of specific characters, for as Löhnis, Mellon, I and others have shown the alternative phases of the same organism can often and probably usually pursue an independent true-to-type existence. It is sometimes urged that such a conception is opposed to the facts of biology. This is not so. It is opposed to much of the traditional teaching of bacteriology, but it is obviously in conformity with the great biological fact that a multitude of different cellular elements, each capable of independent propagation, are commonly derivable from one common germ-plasm. The further back we go in the world of life-forms the more we find the differentiated cell retains its multipotential characters of the original plasm. In the bacteria this retention would seem to be complete. The essential resemblance between the primitive bacterial matrix and the germ-plasm of higher life led me to name the former the bacterioplasm.

The first indications of these facts in regard to the cancer parasite came to me when I discovered that "plasm" rod or globule, minute granule or thread (in this stage strikingly similar to Rickettsia), bacillus or coccus could apparently, depending on the culture medium and other factors, be derived indifferently from the cells of the same piece of cancer. The confirmation of these facts came with the discovery that from the same "plasm" all the different forms were derivable. In this stage the refractile granule is a common index. During this phase the germinating "plasm" is easily mistaken for masses of débris to which the bacterial forms have adhered. As Löhnis has pointed out, in the past it has been commonly looked upon as dirt.

Sir, with the attention now being paid to the cancer parasite I look forward confidently to an early confirmation of these views first published in 1921. For long I have been urging that a similar reorientation of the bacteriological mind would probably quickly resolve the difficulties surrounding typhus, influenza, small-pox, &c. If it be true that Weigl, Breinl, and Fejgin have all succeeded in deriving the *Bacillus proteus* (X 19) commonly associated with typhus from the Rickettsia of typhus, we have the first augury of the unexpected facts which will transpire with the application of this broadened outlook. We can safely prophesy big developments along the same lines in the near future.

That familiar bacteria may possess a filterable phase is suggested by the work of Heymans (*B. anthracis*), Valtis, Vannucci, &c. (*B. tuberculosis*), Almquist (*B. typhosus*), Hort (*meningococcus*), and Löhnis. The very striking investigations of Löhnis make it likely that all bacteria have a filterable mode of life; it may even be that this is the essential parasitic form of all bacteria.

I am, Sir, yours faithfully,
Edinburgh, August 1st, 1925. James Young.

THE PRINCIPLES OF DYNAMIC PSYCHOLOGY.

To the Editor of The Lancet.

Sir,—An opportunity, all too brief, occurred for the discussion of psychotherapy at the meeting reported in your last issue of the Medico-Psychological Association in Birmingham. Some of the opinions then expressed may be taken as typical of the progress the medical profession as a whole has made in the acceptance of the principles. Ten years ago it was difficult to obtain a hearing in medical circles for a paper dealing with the value of suggestion. The successes obtained during the war by the exponents of the Seale Hayne school and others, in the treatment of the conversion neuroses altered this, and the profession was bound to admit that suggestion had a definite therapeutic value. Having thus swallowed suggestion whole the profession appears inclined to rest there. If one may judge by the majority of practitioners one meets, the general attitude may be summed up by some such statement as this. "There are certain somewhat eccentric persons who have the power of curing neurotic conditions by suggestion, and there are certain nasty-minded cranks who believe that they can do good by means of a mystic ritual called psycho-analysis. Anyway, neurotic patients are a nuisance and if a bottle of bromide cannot satisfy them, let them go where they will."

There are those of us, Sir, who hold a different opinion. We say that considering the vast amount of misery, social and economic loss, caused by functional nerve disorders, the apathy of the profession, including most of its teachers, is nothing less than tragic. We know that suggestion at the best can do no more than remove some obvious symptom, and does nothing to enable the patient to adapt himself to his environment. It has no effect on phobias or anxieties, it will not cure the psychasthenic, or remove a tendency to criminal outbreaks. In order to treat such conditions as these one must have a knowledge of the workings of each individual patient's mind. One must recognise the existence of a dynamic Unconscious, and realise that the symptoms represent for each patient the satisfaction of some inner need, the solution of some unconscious mental conflict. We realise that an unhealthy body is not without influence on the mind. We do not minimise the importance of tracking down and eliminating all septic foci. We are aware that a dose of calomel may effectively purge melancholy, but we see too many individuals who have been subjected without benefit to every possible minor and major surgical procedure to believe that the root cause of a neurosis can be somatic.

Surely the time has come when students should not leave the medical schools without having learned something of the principles of dynamic psychology. Men when they go into practice will find themselves daily confronted with conditions which neither medicine nor surgery can solve. They will be consulted by women and men whom no examination, however thorough, will convince that they are not the victims of hidden cancer or tubercle. They will be asked to prescribe for adolescent girls who lose both appetite and sleep unaccountably. Healthy youths will present themselves with tales of woe which do not fit in with anything which the student has learned. These, as well as the readily recognisable hysteric and neurasthenic, will try his patience and waste his time and theirs, before taking their troubles elsewhere, unless he has the necessary psychological knowledge to deal with them. More important still, he will have many opportunities of dealing with the beginnings of neurosis in childhood, but he will pass them by.

The teaching I would advocate need not be definitely committed to the theories of either Freud, Jung, or Adler. Once imbued with the idea of the Unconscious as a dynamic force and not a lumber room, the interested student will pursue the subject on his own lines. I would emphasise, however, that as regards the lecturer, the terms neurologist and psychologist are not interchangeable, and it is for his psychological rather than his neurological knowledge that the lecturer should be chosen. An important part of the course would deal with the training of the young child, as it is during the nursery years that the foundations of most neuroses are laid, but something too would need to be said as to the part played in the anxiety states by the sex life of the adult. I am aware that post-graduate courses on these lines are in existence in some centres, but such lectures touch only the fringe of the profession. Such training as I advocate would at any rate enable the student in after life to recognise these cases when he sees them and enable him to advise treatment, even if he did not care to carry it out himself.

It is a mistake to think that there is no choice between neglect and a formal psycho-analysis. An astonishing amount of psychology can be dispensed over the counter, as it were, with lasting benefit to the recipients. Patients are frequently astonished, but never resentful of questions asked about their sex life, and show themselves extraordinarily grateful if the physician is able to point out where the shoe pinches. A varying amount of mental analysis is required in other cases and sometimes may be combined with suggestion, whilst in some other types the analysis must be carried to rock bottom. These last should be referred to recognised experts, but unless we train our students where are these experts to come from? Already this branch of therapeutics is overrun by men and women who have had no medical training. Some of them are honest and competent workers; others are not so, and bring disrepute upon a science which by its very nature arouses instinctive opposition. The value of psycho-analysis is freely recognised by educationists, the clergy are fully alive to its social uses; how long will the medical profession continue to turn the blind eye?

I am, Sir, yours faithfully,
Birmingham, August 4th. R. Macdonald Ladell.

PUBLIC HEALTH OF MARKET DRAYTON.

To the Editor of The Lancet.

Sir,—I enclose report of a recent conference at Hales Hall (the rural dean in the chair) which throws some light on the causes of high infant mortality for some years past at Market Drayton, but does not solve the question, "Why does the Minister of Health steadily refuse to publish the report as to the high infant mortality at that little town, made by his own medical inspector last autumn?" We infer from a statement made by Dr. Wheatley, the M.O.H. for Shropshire, on May 9th, that "bad housing and ignorance" were the principal causes, and that "the health education" should begin in the elementary school (*Newport and Market Drayton Advertizer*, May 9th, 1925).

At the conference, reported in the issue of the same newspaper on July 25th, we gather that the medical inspector's report recommended more education, probably including the education of mothers at the infant welfare centre, and help for that centre. The report, we are informed, also stated that "the sanitary record is poor"; and it "suggested the appointment of a woman guardian." Surely this report should be published in full; the ratepayers should be told what improvements should be made in administration by the guardians which a woman guardian could assist; ignorance should be dispelled, the interest of the inhabitants enlisted, and the lives of the infants saved.

I am, Sir, yours faithfully,
August 4th, 1925. J. Theodore Dodd, M.A., J.P.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.—We are, Sir, yours faithfully,

J. AND A. CHURCHILL.

7, Great Marlborough-street, London, W.,
July 31st, 1925.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bills Advanced.

ON Tuesday, July 28th, the Mental Deficiency (Amendment) Bill passed through Committee in the House of Lords, and the Dangerous Drugs Bill was read a second time. On the same day in the House of Commons the Diseases of Animals Bill was read a third time. On Wednesday, July 29th, in the House of Lords the Diseases of Animals Bill was read a first time, and the Summer Time Bill and the Dangerous Drugs Bill passed through Committee. On Thursday, July 30th, in the House of Lords the Diseases of Animals Bill was read a second time, the Public Health Bill was considered on report and certain minor amendments were agreed to, and the Mental Deficiency Amendment Bill was read a third time and passed. On Friday, July 31st, in the House of Lords the Public Health Bill was read a third time and passed, and the Pensions Bill and the Diseases of Animals Bill passed through Committee. Among a number of Bills to which the Royal Assent was given by Commission was the Mental Deficiency (Amendment) Bill. In the House of Commons on the same day the Lords amendments to the Therapeutic Substances Bill were agreed to.

HOUSE OF LORDS.

WEDNESDAY, JULY 29TH.

Indian Medical Services.

Lord SYDENHAM asked the Secretary of State for India whether measures were in contemplation adequately to fulfil the medical requirements of the Indian army, British residents, official and non-official, and the civil hospitals, and to secure the progress of medical science in all its branches throughout India. He said that we had conferred immense benefits upon the peoples of India by the introduction of Western medicine and surgery. Since Lord William Bentinck opened the Calcutta Medical College in 1835 the Indian Medical Service had grown to be one of the finest—perhaps even the finest—public medical service ever created. It had produced men who had won world-wide reputation, not only for research into the causes, the spread, and the prevention of diseases which afflicted India, but also for the fine work which had been done in educating the Indian students. While this service had always maintained a very high standard of health in the Indian army, to which it specially ministered, its achievements on the civil side had been most remarkable. The hospital system, which we introduced into India, had been spread broadcast over that country, and had been imitated in very many native States. The Indian Medical Service was in the strictest sense a key service, because it not only conserved the health of all the other British services, but it supplied the directive forces in all that might be called sanitation in India. The Indian Medical Service was crumbling away, and it had been necessary lately to send out medical officers on short contract, which was totally unsuitable to the conditions of India. It was essential that the medical officers of India should know the people and their languages and regard India as providing them with a career. This makeshift system could not possibly answer. In recent years there had been a great many inquiries into medical matters in India. The Royal Commission on the Public Services of 1912–15 in their report published in 1917, stated that the Indian Civil Medical Service was being economically and efficiently performed, which was undoubtedly true at that time. The Verney Lovett Report of 1919 proposed a unified service, to be called the Indian Medical Corps, the Indian Medical Service absorbing the R.A.M.C., and special provision being made for the discharge of the civil duties. The Esher Committee of 1919–20 declared that the Verney Lovett plan was the only feasible scheme of unification, but it decided that the amalgamation of the I.M.S. and the R.A.M.C. was at present impracticable. The Lee Commission of last year proposed that the R.A.M.C. should absorb the I.M.S.—which he believed would give rise to a great many administrative difficulties—and that a civil branch should be created which would be 50 per cent. Indian recruited. The Report alluded rather ominously to the requirements of the provinces for a separate medical service. Those words seemed to show that there had been some political pressure brought to bear on the Commission, and he believed that the best British medical graduates would never join a medical service which would quickly become purely Indian whatever proportion they arbitrarily fixed. Under the Act of 1919 all the medical services were made a transferred subject and subsequently a boycott of the Indian Medical Service officers was set up.

India had produced a limited number of medical men of marked ability, and the subassistant surgeons, a class which we had created, had done much useful work, especially when under British supervision. But India had never shown the aptitude for Western medical science which had distinguished Japan. The ways of Western medical science had not yet won the full confidence of the Indian people, or even of all the educated classes, although Mr. Gandhi, who was the greatest protagonist of Indian methods, was not anxious to be operated on by an Indian surgeon. Vaids and Hakims were still numerous and influential, and they accounted annually for a considerable part of the mortality in India. The Ayurvedic and Unani systems, which were not really systems, were now being subsidised from public funds in some places, and this waste of public money was sure to be increased in the future. If the I.M.S. was not restored there would be a large reversion to indigenous methods, which would have a disastrous effect on the general health in India, and there would also be widespread corruption. India could not at present produce men capable of directing, teaching, and developing an exotic system of medicine and surgery, and besides that caste laws might, and very often did, interfere with the work of the Indian practitioner. Of the very large number of students turned out annually from our medical schools a considerable proportion never made any attempt to practise and many of them became politicians, while a few had specialised in bombs. So far as British men, women, and children in India were concerned they must all feel that it was the duty of the Government to provide them with medical assistance from men of their own race. The Lee Commission admitted this, and proposed to set up districts each possessing a European officer supported in whole or in part at the public expense. If the districts were made small enough this plan might work, but already in some cases great hardship existed through the great distances which separated British people in India from a British doctor. He did not forget the work of the medical missions, of which he saw a great deal. They also were bringing Western science to the people of India, and perhaps especially to the women of India who were in dire need of it. The difficulties in finding a solution of many of the present problems were very great in view of the hostility towards British officials, British methods, and British science, which had been generated in recent years. He disliked and distrusted centralisation, but he was convinced that the general control of any civil medical service in India, of medical education, and of medical research must be retained in the hands of the Imperial Government. Failing this there would certainly be a general reaction and a fatal lowering of standards in the whole administration of the medical services throughout India.

The EARL of BIRKENHEAD (Secretary of State for India) said that the Indian Medical Service and its organisation had always been a question of extreme difficulty. It was at once a military and a civil medical service, and the interests of the two branches had not always been the same. The cardinal fact was that, generally speaking, the civil medical administration of India in the provinces, including the administration of hospitals, public health, and the provision for medical education, was a Provincial Transferred Subject under the Act of 1919, and the Secretary of State had divested himself of the powers of superintendence and control which he formerly exercised with regard to it. The Lee Commission, subject to certain limitations, took the same line with the Indian Medical Service as with the other all-India services dealing with transferred subjects. It appeared to them to be the logical and practical sequence of the reforms that, subject to the reservation of the rights of present members of the service, the provincial governments should in future recruit and control the services for whose work they were responsible to the Provincial Legislatures. In the case of the Indian Medical Service, however, the general principle was limited by two important considerations: first, the Civil Medical Service was the only source from which a medical reserve for the needs of the army, and in particular its requirements in trained British medical men, could be easily obtained in emergency; secondly, he had decided to adopt the recommendations of the Lee Commission for the provision for European services of medical attendance by British medical men. In the light of what he had said it would be clear that the Secretary of State would no longer undertake to recruit officers for the medical administration in

India generally or, in particular, for civil hospitals as such. Nor could he assume responsibility for the medical care of British non-officials resident in India. But the Act left as "Central Subjects," for which the Government of India were responsible, a number of matters, for instance, central agencies for research and technical training and the promotion of special studies, and a reserved responsibility in regard to legislation for infectious diseases and the regulation of medical qualifications and standards. For these the Secretary of State remained responsible, and he would continue to recruit officers to deal with them. He would also, of course, recruit for the civil medical needs of administrations that remained directly under the Government of India and for the Political Department. There remained for consideration the provisions to be made (1) for the army, including its medical reserve, and (2) for medical attendance on the European services as recommended by the Lee Commission. He had received the recommendations of the Government of India on these matters, and their consideration was already well advanced in his department. He was not yet in a position to communicate his final decisions, but he might, perhaps, indicate the lines on which he thought a solution of this difficult question would be found. The Lee Commission, with some hesitation, for they realised that military organisation lay outside their terms of reference, recommended that the military side of the Indian Medical Service should be absorbed in the Royal Army Medical Corps. The proposal had received very careful consideration from the Government of India and himself, and they had come to the conclusion that the solution proposed would raise many more difficulties on the military side than it would solve. They, therefore, thought that the Indian Medical Service must be maintained. It would be essentially a military service, but its reserve would be secured by lending officers to the civil administration. A consideration of the numbers in question went to show that the number of European officers in the reserve so lent would be sufficient to provide for the needs of the European services on the lines of the scheme proposed by the Lee Commission. These officers would be stationed at the headquarters of groups of districts throughout India, and would be made available for the European services and their families. The officers required by the Government of India for the central medical subjects would also be obtained from the Military Indian Medical Service.

It was, of course, a matter of the first importance whether a service constituted on these lines would attract recruits of the right class. He was inclined to think that it would be essential, with this in view, to reserve for the portion of the army reserve lent to the civil side but not required directly for the medical care of the British services, a number of civil appointments; for instance, research or professorial appointments. Such appointments had always been one of the attractions of the Indian Medical Service, and if the essential army reserve maintained in civil employment allowed a margin, as it almost certainly would, it was clearly a gain not only from the point of view of recruiting inducements, but a gain to Indian public health generally that they should be employed in the departments of research and teaching in which their predecessors had done so much for the welfare of India. His statement was necessarily tentative, for the final conclusion could only be reached after a careful balancing of the various interests involved, and, in particular, the claims of the Local Governments to the control of the provincial medical administration. But he was hopeful that a solution might be found on these lines, and that it would appeal to the medical profession. He was the more optimistic on the last point because, unlike certain other services, the Indian Medical Service was at present obtaining recruits of a high standard from the medical profession in this country, notwithstanding the uncertainty of the position pending his decision.

HOUSE OF COMMONS.

Wednesday, July 29th.

Appointment of Medical Service Chairmen.

Mr. **Meller** asked the Minister of Health (1) what was the present procedure for appointing the chairmen of the medical service, the pharmaceutical service, and the joint services subcommittees of an insurance committee; whether such procedure had worked effectively since the inception of the National Health Insurance Act; and whether he had received any request from an insurance committee for amending the present regulations; and (2) whether he had received from the insurance committee for the County of London a representation protesting against the National Health Insurance (Medical Benefit) Amendment Regulations (No. 2), 1925, which provided for the appointment of the chairman of the medical service subcommittee by the Minister of Health failing the unanimous vote of the subcommittee, and that such member might not be a member of the insurance committee; and what action he proposed to take.—Sir **Kingsley Wood** (Parliamentary Secretary to the Ministry of Health) replied: Under the previous Regulations the chairman of the medical service subcommittee was required to be elected by the approved society representatives on the subcommittee and the medical practitioners appointed to be members of it, or in default of any selection by them by the neutral members of the insurance committee. No request for an amendment of the Regulations has been received from any insurance committee, but in London failure to find a chairman commanding the confidence of both parties led to the withdrawal of the medical representatives and the machinery for the investigation of complaints was brought to a standstill. A similar situation has arisen recently in Southampton. The amending regulations of July, 1925, arose out of the difficulty in London, and represented a settlement which my right hon. friend understood to be acceptable to both parties to the dispute. My right hon. friend has recently received representations from the London Insurance Committee against the new regulations, but he can see no other method of preventing the recurrence in future of a deadlock which is prejudicial to the administration of medical benefit and to the interests of insured persons.

Thursday, July 30th.

Pensioners Medical History Précis.

Mr. **Hayes** asked the Minister of Pensions whether, in cases of appeal by a widow or orphan children of an ex-Service man whose medical history disclosed venereal disease, he would sanction the omission of all reference thereto from the précis sent to the widow or other appellant when such disease had no relationship to the cause of death.—Major G. C. **Tryon** replied: It has been the consistent policy of the Ministry, reinforced by repeated representations, to make a précis in a case of appeal a complete statement of the man's medical history as known to the Ministry, in order that the tribunal may have before it precisely the same and as full information as that on which the Ministry came to their decision. The Ministry are not in a position to determine the view which the tribunal may take as regards the connexion between the cause of death and any other disease of which there is evidence in the man's medical history. The case for presenting a complete statement to the tribunal is in my view so important that I could not authorise any exception to the rule.

Veterinary Inspection of Dairy Herds.

Mr. **MacKenzie Livingstone** asked the Minister of Health what local authorities now carried out veterinary inspection of dairy herds.—Mr. **Neville Chamberlain** replied: A few of the sanitary authorities in England and Wales systematically carry out veterinary inspections of dairy herds, and I believe that most sanitary authorities have made arrangements for obtaining the services of a veterinary surgeon for the inspection of cattle where occasion demands.

Industrial Hygiene.

Colonel **Woodcock** asked the Minister of Labour whether any effect had been given to the unanimous resolution of the conference of the International Labour Organisation, Washington, 1919, that an advisory committee on which the governments, the employers, and the workers should all be represented, should be appointed without delay to keep in touch with the work of the health section of the International Labour Organisation.—Mr. **Betterton** (Parliamentary Secretary to the Ministry of Labour) replied: So far as I have been able to ascertain up to the present the only committee appointed as a result of the Washington resolution to which my hon. and gallant friend refers is the Correspondence Committee on Industrial Hygiene. That Committee, however, consists of experts and not as laid down by the Washington resolution of representatives of governments, employers, and workers.

Tuesday, August 4th.

Deaths from Small-pox.

Mr. **Broad** asked the Minister of Health whether the Registrar-General would revise his figures for 1924 in regard to small-pox deaths, in the light of the information given in the recent Report of Sir George Newman, in which five of the small-pox deaths were transferred to other classifications, it being the opinion of the certifying doctor that small-pox was not the cause of death.—Mr. **Neville Chamberlain** replied: I understand that in the case of all the deaths in question small-pox is certified by the certifying doctor as being one of the causes of death. In such cases the selection from among several certified causes of the particular cause under which the death is classified for statistical purposes is governed by general rules, based upon international agreement, which in this country provide that deaths should be classed to small-pox if this disease is included among the certified causes. I see no reason for revising the classification in the case of these particular deaths, especially since full information regarding them is already given in the chief medical officer's report.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary quarterly Comitia of the College was held on July 30th the President, Sir Humphry Rolleston being in the chair The minutes of the Censors Board were read The following successful candidates were admitted as Members:—

Drs Henry K. Bates Robert H Baxter John Brander Edward A Carmichael Peter Connan, John H Dunn Edward Gallop Humphry H. Gleave Frank D Hewitt Redvers N Ironside Victor J F Lack, Reginald C Lightwood, James L. Livingstone Neville I Lloyd, George L Lyon Smith Bruce Maclean Cyril C. W Maguin Frederick H Moran Bernard E. Schlesinger John S. Sloper Harry L. Stokes Robert Y Stones Samson Wright and Harry W Wunderly

The following College officers members of committees and examiners were elected for the ensuing year:—

Censors—Sir John Rose Bradford Dr Cyril Ogle Dr James Calvert and Dr *Robert Hutchison*

Emeritus Treasurer—Sir Dyce Duckworth.

Treasurer—Dr Sidney P Phillips

Registrar—Dr Raymond Crawfurd.

Harveian Librarian—Dr T H Arnold Chaplin

Members of the Library Committee—Dr Frederick Parkes Weber Dr Herbert Spencer Dr William C Bosanquet and Dr Charles J Singer

Curators of the Museum—Dr John Mitchell Bruce, Sir Seymour John Sharkey, Sir Frederick W Andrewes and Dr William Hunter

Finance Committee—Dr Arthur George Phear Dr John Fawcett and Dr Frederick J Poynton

Examiners.—Chemistry: Dr Robert H A Plimmer and Dr William H Hurtley Physics: Dr William E. Curtis and Dr. Sidney Russ Practical Pharmacy Dr Edward A. Cockayne Dr Nathan Mutch Dr Alfred J Clark Dr Hugh Gainsborough and Dr *Orlando Inchley* Physiology Dr John B Leathes and Dr John Mellanby Anatomy: Dr G Elliot Smith Medical Anatomy and Principles and Practice of Medicine Dr H Morley Fletcher Dr Arthur G Phear, Dr William C. Bosanquet Dr James W Russell Dr Charles R. Box *Sir James Purves Stewart* Dr Lewis A Smith Sir John C Briscoe Dr Charles E. Lakin and Dr James A Torrens Midwifery and Diseases peculiar to Women Dr Cuthbert H J Lockyer, Sir Ewen J Maclean, Sir Henry J F Simson Dr William Gilliatt and Dr Stanley Dodd.

Examiners in Public Health—Part I Mr John H Ryffel Part II. Dr David S. Davies.

Tropical Medicine—Sir Percy W Bassett-Smith (Bacteriology): Sir Leonard Rogers (Diseases and Hygiene of the Tropics)

Ophthalmic Medicine and Surgery—Dr James S. Collier

Psychological Medicine—Part I Dr Eric D Macnamara Part II.: Dr Robert P Smith and Dr C. M Hinds Howell.

Laryngology and Otology—Sir StClair Thomson

Licences to practise Physic were granted to the following candidates, who have passed the Final Examination of the Conjoint Board, and are now entitled to receive the conjoint diploma:—

Ahmed K. Abdel Khalik, Cairo Geoffrey N M. Aitkens Charing Cross John S. * Under the Medical Act 1876

The undermentioned diplomas were granted, jointly with the Royal College of Surgeons of England, to the following successful candidates :—

Diploma in Public Health.—Charles O. S. B. Brooke, Dorothy M. Campbell-Meiklejohn, John V. Carroll, Joseph Cauchi, Edward T. P. Eames, David G. M. Edwards, John C. N. Harris, Strafford S. Hewitt, Alice E. D. Karn, Burjor F. Khambatta, Chandu V. Ramchandani, Bisheshwar P. Srivastava, Doris M. Stone, and Frederick Tooth.

Diploma in Tropical Medicine and Hygiene.—Ahmed F. Abbassi, Mohamed Ali, Donald D. Anderson, John B. S. Baxter, John C. R. Buchanan, Matthew Burn, Angus H. Campbell, Robert A. Chambers, William Corner, John R. Davies, Gilbert H. Dive, Ibrahim Girgis, Francis M. Halley, Hans-Raj, George W. Harley, Alan McKenzie, Mir S. Mahmood, William J. Moir, Charles R. Philip, Louis M. J. R. Pilot, Sundramier Ramakrishnan, Hugh D. C. Rice, George W. Scott, Edward A. Seagar, Timothy F. Sheehan, Charlotte A. Stuart, Clement Sturton, and W. Wilkinson.

Diploma in Psychological Medicine.—Geoffrey T. Baker, George L. Cutts, Henry T. Jones, John J. Laws, John B. S. Lewis, Hugh C. McManus, Andrew H. Pearce, Gordon F. Peters, Reginald G. Riches, Gerald R. A. de Montjoie Rudolf, and John Russell.

Diploma in Ophthalmic Medicine and Surgery.—Edward W. Arndt, Harnand L. Batra, Kashinath D. Bhave, Catharine Boyd, Martin M. Cruickshank, Arthur W. D'Ombrain, Agnes Estcourt-Oswald, James A. F. Flynn, Kenneth B. Johnston, Wajid Ali Khan, Coimbatore V. Krishnaswami, Arthur P. Lawrence, Arthur L. McCurry, William M. C. MacDonald, Kizhakkekalattil K. Nayar, Kaikhushru B. Palkhivala, and Reuben W. Payne.

Diploma in Laryngology and Otology.—Sok Nin Chau, Edward D. D. Dickson, Robert McM. Glynn, Ronald E. Jowett, Jean P. Kies, Norman W. MacKeith, and John H. Shaw.

By-law 112, relating to the age of candidates for the Membership, was altered to read as follows: "Every candidate for the Membership shall furnish proof of having attained the age of 23 years."

The Baly Medal was awarded to Prof. R. Magnus, of Utrecht, on the recommendation of Council.—The President announced that he had appointed Sir John Rose Bradford to deliver the Harveian Oration in 1926.—A report was received from the Representative of the College on the General Medical Council concerning the proceedings of the Council at their session held in May and June last.—A report was received, dated May 29th, 1925, from Dr. Gordon Holmes, Representative of the College at the Charcot Centenary in Paris.—A report was received from Sir Percival Horton-Smith Hartley, Representative of the College at the Eleventh Conference of the National Association for the Prevention of Tuberculosis on July 6th and 7th.—A report was received from Dr. Dawtrey Drewitt, the Representative of the College on the Chelsea Physic Garden.—Sir Frederick Andrewes was reappointed a Representative on the Executive Committee of the Imperial Cancer Research Fund.—A report was received from the Committee appointed to revise the by-laws and regulations relating to the examination for the Membership.—After some further College business of formal nature, the President dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the College on July 30th, Sir John Bland-Sutton, the President, in the chair, Prof. Alexander Primrose was admitted a Fellow of the College, Mr. Evelyn Sprawson was re-elected a Member of the Board of Examiners in Dental Surgery, and Sir D'Arcy Power was re-elected a Member of the Executive Committee of the Imperial Cancer Research Fund.—The terms of a petition for a supplemental charter were taken into consideration and approved, and it was decided that the further steps to be taken in the matter should be considered at the quarterly meeting of the Council in October. The proposed supplemental charter is, in general terms, to enable the Council to make improved arrangements for certain examinations. In accordance with this subject it is proposed to give the Council power to increase the number of members of the Court of Examiners and to give greater freedom in the selection of examiners for the Licence in Dental Surgery. It is also proposed to admit women Fellows and Members of the College and Licentiates in Dental Surgery on the same terms and conditions as men and with the same rights and privileges and to effect certain minor adjustments.—The diploma of Fellow was conferred upon the following three candidates who have now complied with the necessary by-laws: Drs. John P. Hosford, Alec A. Lees, and Donald E. Ross.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the undermentioned subjects :—

Surgery.—S. J. Alexander, Sydney and St. George's Hosp.; S. Bartlett, Liverpool; F. Beinaschewitsch, Berne; F. Carroll, St. Mary's Hosp.; W. Hinds, Durham; and P. H. Knowles, Bristol.

Medicine.—S. Bartlett, Liverpool; F. T. Birkinshaw, Univ. Coll. Hosp.; A. H. Henson, Charing Cross Hosp.; A. Kaplan, St. Mary's Hosp.; T. A. Lazaro, St. Bart.'s Hosp.; C. H. Mason and C. S. Netscher, St. Mary's Hosp.; R. C. Pratt, Birmingham; and K. E. R. Robertson, St. Mary's Hosp.

Forensic Medicine.—S. Bartlett, Liverpool; T. A. Lazaro, St. Bart.'s Hosp.; R. D. Mason, St. Mary's Hosp.; P. B. P. Mellows, St. Bart.'s Hosp.; J. M. Moran, Manchester; and K. E. R. Robertson, St. Mary's Hosp.

Midwifery.—S. Bartlett, Liverpool; S. A. Joelson, London Hosp.; C. H. St. Johnston, Birmingham; J. Mindess, London Hosp.; J. M. Moran, Manchester; and P. H. Row, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: S. J. Alexander, S. Bartlett, F. T. Birkinshaw, F. Carroll, A. Kaplan, P. H. Knowles, C. H. Mason, C. S. Netscher, and K. E. R. Robertson.

THE Royal Free Hospital has received a gift of £2000 from an anonymous donor for the enlargement of its light treatment department.

KING'S COLLEGE HOSPITAL.—In 1922 the scholars and staff of the Mary Datchelor girls' school at Camberwell raised £650 in connexion with the London Schools' Hospital Fund towards the £1000 required for the endowment of a bed in King's College Hospital. The fund has now been completed and last week the Bishop of Kingston dedicated the bed. In 1912 the old girls endowed a cot at the hospital.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The Commission, having held 40 meetings at weekly or shorter intervals since October last for the hearing of oral evidence, have now adjourned until October next, when the final evidence from representatives of the Government departments will be taken, after which the Commission will proceed to consider their report. Proof copies of the oral evidence and the relative statements submitted at the meetings of June 25th (3*s.*) and 30th, and July 2nd and 7th (each 2*s.* 3*d.*), as well as Volume II. of the Minutes of Evidence, covering the period from Jan. 15th to March 26th (12*s.* 6*d.*), are on sale at H.M. Stationery Office.

TUBERCULOSIS IN WALES.—The Board of Governors of King Edward VII. Welsh National Memorial Association for the Prevention, Treatment, and Abolition of Tuberculosis met for the first time since its formation in 1912 for its annual meeting at Bangor on July 30th. The President stated in his opening address that English local authorities were being treated more generously than the Welsh Association. The Association had provided 1400 beds at an average cost of £322 per bed, including the cost of X ray installations, operating theatres, and other necessaries. Treasury grants had not amounted to more than £166 per bed, while the Corporation of Manchester for its tuberculosis scheme would receive, he said, grants at the rate of £525 from the Treasury. The annual statistics of the work of the Association during the past year showed that the number of people examined at the dispensaries and visiting stations was not quite so large as in the preceding year. During last year in hospitals or sanatoriums, 4480 patients were treated. The Association now had 1400 beds in their own institutions. In 1911 there were 3063 deaths from tuberculosis in Wales and Monmouth, and in 1921 the number was 3180, while the population in that period had increased by 300,000—i.e., for every million persons living in Wales and Monmouth in 1911 there were 1513 deaths from tuberculosis, while in 1924 the deaths per 1,000,000 numbered 1169. In the five westernmost counties—Pembrokeshire, Cardiganshire, Merionethshire, Carnarvonshire, and Anglesey—the death-rate per 1,000,000 persons in 1924 was 1664. In the other eight counties the rate was 986. The need for more beds, particularly for persons suffering from surgical tuberculosis, was strongly emphasised. Mr. J. C. Townley emphasised the incidence of tuberculosis in the three western counties, Merioneth, Cardiganshire, and Carnarvon. The contrast in the death-rates from tuberculosis was most marked between the eastern and western counties and even between the east and west districts of the counties themselves. In Carnarvon the deaths from tuberculosis ranged from 6 per 10,000 in Conway rural area to 28 in Gwyrfai and 26 in Glasfryn. In the part of Montgomeryshire which bordered Merioneth the rate was 6, while in the adjoining rural area of Dolgelly in Merioneth it was 14, and farther west it was 19. Colonel Lyle Cummins, the principal medical officer of the Association, said one satisfactory feature in relation to the three counties was that, while their mortality from tuberculosis started higher than other counties, the decline in the death-rate had been as pronounced as in the remainder. Several theories had been propounded to account for the greater susceptibility of the western counties to tuberculosis, including the prevalence of rain bearing winds, especially westerly winds. Another suggestion was that people living *in isolated districts had a lesser power of resistance than those* living in congested town areas, where they became more immune from attack and their resisting powers increased

DUBLIN: POST GRADUATE CLASSES —Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept 14th, to Saturday, Oct. 3rd Members of the class can reside in college rooms and dine on commons.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION —Queen Mary's Hospital will hold a general course in Medicine, Surgery, and the Special Departments from August 24th to Sept. 5th. Daily sessions will be held from 10.30 A.M. to 5 P.M., including demonstrations of clinical methods, groups of illustrative cases, &c. A special feature of the course will be the opportunity for practical study in gynæcology and obstetrics.—A variety of special courses will be held during the month of September From the 7th, continuing for five weeks, will be given an Operative Surgery course arranged by the Seamen's Hospital, the meetings taking place four times weekly —On Sept. 21st the Brompton Hospital begins a two weeks' course dealing with Pulmonary Diseases from all aspects —There will be an afternoon course with evening V D clinics at the Blackfriars Skin Hospital from Sept 7th to 19th.—The same date has been chosen for a course to take place at the Infants Hospital A special feature of this is the instruction available in all the latest methods employed for dealing with infant ailments, and facilities are provided for visits to centres away from the hospital —The Royal Westminster Ophthalmic Hospital has fixed a course from Sept 7th to 26th, consisting of instruction in the out-patient department and special lectures and demonstrations dealing with Diseases of the Eye —There will be an intensive course in General Medicine, Surgery, and the Specialties at the Westminster Hospital from Sept. 21st to Oct. 3rd —Dr C B Heald has undertaken a series of lecture-demonstrations in Electro-therapy, on Wednesdays, beginning Sept. 23rd, at the Royal Free Hospital.—Copies of the syllabus of each of the aforementioned courses, together with the general programme of the Fellowship of Medicine, can be obtained from the Secretary to the Fellowship at 1, Wimpole-street, London, W 1

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION 1, Wimpole-street, W

MONDAY, August 10th, to SATURDAY, August 15th.—PRINCE OF WALES'S HOSPITAL, Tottenham, N (N E. London Post-Graduate College) Intensive Course in General Medicine, Surgery, and the Special Departments. Sessions 10 30 A.M. to 5 30 P.M., except Saturday (second week) —ALL SAINTS HOSPITAL, Vauxhall Bridge-road, S.W Special Course in Urology, consisting of clinical instruction and special lecture on subject.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck street. Lecture-demonstrations illustrated by cases at 5 P.M Monday, Dr L. R. Yealland on The Varieties of Muscular Atrophy Tuesday, Dr Hildred Carlill on The Reflexes in *Health and Disease* Wednesday, Mr C. Wakeley, on Cerebral Surgery Thursday, Dr E. D Macnamara on The Sequelæ of Encephalitis Lethargica Friday Dr C. Worster-Drought on Diagnosis and Treatment of Syphilis of the Nervous System

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith W

MONDAY August 10th.—11 A.M. Surgical Registrar: Surgical Wards 2 P.M Dr Scott Pinchin: Medical Out patients. 3 P.M., Dr Saunders Medical Wards

TUESDAY —11 A.M., Dr McDougal Electrical Dept. 11 A.M. Mr Endean Venereal Diseases 2 P.M., Dr Burrell Chest Cases.

WEDNESDAY —10 A.M Dr Saunders: Medical Diseases of Children 2 P.M Dr Dowling: Skin Dept 2 P.M., Mr Gibb: Eye Dept

THURSDAY —11 A.M Sir Henry Simson: Gynæcological Wards 12 noon Surgical Registrar Surgical Pathology

FRIDAY —2 P.M., Dr Burrell Medical Out patients 2 P.M Mr Sinclair Surgical Out patients. 2 P.M., Mr Vlasto Throat, Nose, and Ear Dept

SATURDAY —10 A.M., Dr Saunders Medical Diseases of Children

Daily, 10 A.M to 6 P.M., Saturdays 10 A.M to 1 P.M., In patients, Out patients, Operations, Special Departments

Appointments.

BUSH W H., L.M S.S.A., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Chulmleigh, Devon

DONNELLY, N M., M.B., B Ch. R.U.I D P H., Assistant Medical Officer and Tuberculosis Officer for Deptford

MOXON, F., M.B., B S Durh., Ophthalmic Surgeon, The Nelson Hospital, Merton.

TURNER, EILEEN M., M.B., B S Lond., Assistant Medical Officer of Health and Assistant School Medical Officer, Holland, Lincs.

Manchester Royal Infirmary SHIRK, F H., M B., Ch.B., MARSHALL, C T., M B., Ch B., YOUNG, N., M.B., Ch B., and MUCKLOW, S. L., M.B., Ch.B, House Physicians, LANGFORD, C. F., M.B., Ch.B., BOLTON, N. W., M B., Ch.B., BOOTH, G H H., M.B., Ch.B., WOOD, R., M B., Ch B., and SEED, N F., M.B., Ch.B., House Surgeons, PENMAN, H., M.B., Ch.B., House Surgeon to Special Department, MUMFORD, P B., M.B., Ch.B., Assistant in the Dermatological Department; and JOHNSON, M., M.B., Ch B Surgical Clinical Assistant

Vacancies.

For further information refer to the advertisement columns.

Birkenhead Borough Hospital —Third H S £100

Bristol, Cossham Memorial Hospital, Kingswood.—Res M.O £150

Carlisle, Cumberland Infirmary —H P, &c, at rate of £165 Also Jun H S at rate of £135

Derby, Royal Derby and Derbyshire Nursing and Sanitary Association.—Hon Obstet P

Derbyshire County Council —Asst Sch. M O and Tub O £650

Jersey General Hospital and Poor-law Infirmary —Res M O £200

Liverpool County Borough.—Jun Asst. Sch. M.O £600

Manchester and Salford Hospital for Skin Diseases —H S £100

Newcastle-upon Tyne, Princess Mary Maternity Hospital —Asst. Res M.O at rate of £40

Plymouth Borough.—Asst M O H £600

Royal Free Hospital, Gray's Inn-road, W C —Cas. O £150

St Bartholomew's Hospital.—Ophthalmic S and Phys Accoucheur

St Peter's Hospital for Stone, &c Henrietta street, Covent Garden W C —H S, at rate of £75

Sudan Government Wellcome Tropical Research Labs Khartoum —Asst Bacteriologist £720

Sunderland Royal Infirmary —H.P, £140

Sunderland Royal Infirmary and Children's Hospital —Hon S for Ear Nose, and Throat

Warrington Infirmary and Dispensary —Jun H S. £175

West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park N W —Sen H P at rate of £150

West Riding County Council.—Dist Tub O for Barnsley £600

The Chief Inspector of Factories Home Office, London, S W, announces a vacant appointment for a Certifying Factory Surgeon at Maesteg (Glam.)

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906 for the Districts of the Aberayron, Cardigan &c. (Circuit No 31) Applications should reach the Private Secretary, Home Office, not later than August 22nd

Births, Marriages, and Deaths.

BIRTHS.

SATOW —On July 20th, at "Ackland" Oxford, the wife of Lawrence L. Satow, M C., M R C.S., of a son

MARRIAGES

HILL—VARLEY —On July 28th, at the Congregational Church St Leonards-on Sea Humphrey Cheetham Hill M B., B Ch. to Hilda Frances fourth daughter of Rev and Mrs Henry Varley of St Leonards.

LODGE—CRESSWELL.—On July 27th, at the Parish Church of St Mary the Virgin Burley-in Wharfedale Samuel Durham Lodge, F R.C S. to Margaret Ianthe Edgar Alston, eldest daughter of Lionel Cresswell J.P., Barrister-at Law, and Mrs Cresswell of The Hall, Burley-in Wharfedale

POTTS—HEPWORTH.—On July 30th at Brompton Parish Church South Kensington Dr John Leonard Potts to Nancy May younger daughter of Mr and Mrs Allan Hepworth, of Ealing

DEATHS

BUNNY —On July 23rd Joseph Brice Bunny, L.R C.P., M R.C S., of Victoria park, Weston-super Mare (formerly of Newbury) aged 78

N.B —A fee of 7s. 6d. is charged for the insertion of Notices of Births Marriages and Deaths.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN THE NEW HEBRIDES.

A DECLINING NATIVE POPULATION.

Mr. M. King, C.M.G., British Resident Commissioner, in his report for 1923, remarks that the New Hebrides, to which are attached the Banks and Torres Islands, have an area of about 5700 square miles. The natives are Melanesians, but in places there is a mixture of Polynesian blood. There is little change to be recorded in the numbers and composition of the non-native population of the group, the total of French nationality being 709 and of British 275. In regard to the gradual decrease in the native population, Mr. King thinks that of the many reasons assigned for it, those assigned by the late Dr. W. H. R. Rivers, F.R.S., than whom none was more competent to speak, are the most worthy of consideration. He attributed the decline of the Melanesian population to this: "That the people have been deprived of nearly all that gives interest to their lives, and this loss of interest has been brought about by the unintelligent and indiscriminating action of Europeans towards native institutions." The Resident Commissioner proceeds: "I will not quote further, but would invite attention to the original essay in the work referred to ('Essay on the Depopulation of Melanesia,' Cambridge University Press, 1922). The lack of intelligence displayed by would-be civilisers in their action towards natives and native institutions has often impressed itself upon me. The action of such people appears never to be guided by consideration of the effects, positive or negative, good or ill, of such institutions on the native mind or character. The fact that the natives take interest in, and derive pleasure from, such or such an institution, seems sufficient to ensure its discouragement and ultimate suppression. To many of these institutions the natives have been strongly attached, and the blank in their lives left by their discontinuance or suppression is one that cannot be filled."

In most of the islands of the New Hebrides there is a great disproportion between the numbers of the two sexes, males in all cases predominating. Figures collected not long since by the Rev. M. Frater, of the Presbyterian Mission, relating to the population of two of the larger islands and of seven smaller ones, reveal disproportions ranging 5 to 30 per cent., the aggregate of males being 6508 and of females 5408. The general opinion for long was that this preponderance of males in northern islands is due chiefly to female infanticide, ill-treatment of female infants, the premature marriage of girls, and other preventable causes. Careful inquiry has, however, revealed the fact that, while the influences cited have a powerful effect, there is another and probably the chief one, and that is that the excess, as Mr. Frater writes, "begins at birth and is determined by prenatal causes. The male largely out-number the female births, and through the operation of the other causes the disparity between the sexes becomes more marked in adolescence and adult life." This may also be one of the non-contributory causes of the general decline of the native population. As opposed, however, to the experience of the northern islands, a census of the scanty native population of Efate and the adjacent small islands, also made, and very recently by Mr. Frater, revealed a distinct preponderance of females, but not to the same extent as noticed in the case of the males of the northern islands.

The Mission Hospital on Iririki (John G. Paton Memorial) continued its good work, as did the French Government Hospital in Vila. Unfortunately, the departure of the medical officer in charge necessitated the suspension of active operations by the first named before the end of the year. During the months it was open the number of in-patients was 482 (Europeans 17 and natives 465), and the out-patients numbered 902. At the French institution 870 in-patients were treated (Europeans 154 and natives 716), and out-patients to the number of 1065. The deaths in the British hospital numbered 33, 2 being Europeans, and in the French 42, 3 being Europeans. At the French hospital in the Canal de Segond (Santo) many natives benefited from the care of the Condominium medical officer. The Mission Hospital on the island of Tanna has been reopened and much good work has been done by Dr. Williams, the medical officer in charge. It is to be regretted that the arrangement made by the mission authorities was for a few months only. A complete hospital on the island of Ambrym was destroyed by the great volcanic eruption of 1913. The authorities of the mission fund which supported this institution have, it is learnt, decided to replace the destroyed building by another to be erected on the east coast of the island of Malekula. This project, if carried out, will supply a long-felt want, the destruction of the Ambrym institution having left the northern part of the group entirely unprovided in this respect. Influenza, fortunately not of the pneumonic type, and dysentery have claimed their usual toll of native victims.

A LIST OF SANATORIA.

THE Ministry of Health has issued a new list, 10(b), dated July, 1925, price 2*d*., enumerating the sanatoria and other residential institutions approved for the treatment of persons suffering from tuberculosis. This list, which takes the place of an earlier list, 10(*a*), dated April, 1923, applies to residents in England and Wales, and gives the names of the administrative counties and county boroughs in which the institutions are situated. The list distinguishes institutions where admission is restricted as regards class of disease and sex and gives in each case the date on which ministerial approval expires.

CLITORIDECTOMY IN OLD CALABAR.

IN a note on the custom of fattening up the girls of marriageable age among the Efik tribe at Old Calabar, Mr. L. W. G. Malcolm, in the August issue of *Man*, gives some particulars in regard to the operation of clitoridectomy, usually performed by the mother. The fattening-up process takes place at the age of puberty when the girl is secluded for from six months to two years, the period depending on the social position of the parents. The "surgical" operation takes place at or near the end of the girl's period of seclusion. "A piece of coconut shell is shaved very thin and a hole bored through. The glans clitoridis is drawn through this hole and cut off with a sharp knife or splinter of glass. It is believed that the operation has the effect of making the girl sterile. Notwithstanding this the women themselves are the chief supporters of the custom and resent any interference." The note also shows by reproductions of photographs the remarkable effect produced by eating vast quantities of fat-producing foods, including pounded yams cooked in palm oil.

ORGANISED VOLUNTARY CHILD WELFARE.

THE annual report of the Central Council for Infant and Child Welfare for the year ending April 1st, 1925, is a record of steady advance in many directions. In addition to its activities as a centre of information the work of the Central Council included the organisation, in conjunction with the British Red Cross Society, of a day nursery at the British Empire Exhibition at Wembley. This nursery proved a most successful piece of pioneer work, since during the time it was open it cared for no less than 11,091 children.

Another scarcely less important development during the year was the reorganisation and extension of the Travelling Exhibition, which has been in such demand that it was found necessary to collect a duplicate. Bookings were received for every month except April and December when the exhibitions were, for various reasons, not available. The educational value of these exhibitions can hardly be overestimated. In Blackburn 30,000 people visited it during the ten days it was on view, and the attendances at many other places were equally good. A permanent exhibition is now being collected at Carnegie House in response to a widely expressed desire, in which model exhibits of maternal and child welfare work will be on view daily to those interested free of charge. The exhibits included model garments for expectant mothers as well as for infants and children; a dental section, with diagrams showing the effect of diet on the development of the teeth; a clean milk section; a diet section; a rickets section, with exhibit from the Lister Institute of Preventive Medicine; a tuberculosis section; a cripple section; a chamber of horrors; posters, both English and American; an Indian section; and a model of a Red Cross child welfare centre.

A valuable innovation has been the provisional arrangement entered into with the College of Nursing, whereby the Library of Nursing is to be available to borrowers recommended by the Central Council, the Council contributing an annual sum to cover the extra cost of books purchased and the expense of administration. The scheme appears to be working well, and should enable students and infant welfare workers to obtain the best and most up-to-date publications on any branch of public health work.

Brief reports are given of the work of the federations of infant welfare centres throughout the country, as well as of the various constituent societies of the Central Council. In each case the record is one of progress and development.

INDEX TO "THE LANCET," VOL. I., 1925.

THE Index and Title-page to Vol. I., 1925, which was completed with the issue of June 27th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

SOME

Practical Considerations

IN THE CONSERVATIVE TREATMENT OF

FRACTURES OF THE PELVIS AND LOWER EXTREMITY.*

A Course of Four Lectures delivered for the University of London at St. Bartholomew's Hospital

By Sir WILLIAM I. de COURCY WHEELER,
M.D. Dub., F.R.C.S. Irel.,
PAST PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

LECTURE I.

In these lectures I will allude only to the management of cases of fracture of the lower extremity, directing my remarks to those who will have to deal with them under conditions where elaborate apparatus cannot be obtained by a nod, where highly skilled consultants are not always available, and where the results of after-treatment depend largely upon the doctor himself.

Fractures of the Pelvis.

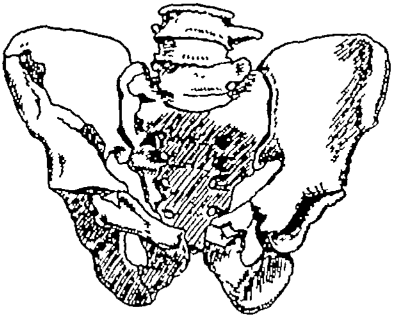
General Considerations.—When I was a student I was taught by the late Prof. E. H. Bennett—a really great authority on the subject of fractures—that extensive fractures of the pelvis were rare and that recovery seldom followed. Twenty-five years have elapsed. Under modern conditions both statements must be amended. Fractures of the pelvis have increased in frequency with the development of industrial machinery and rapid transport, for the crushing injuries associated with accidents to motor-cars, aeroplanes, and those employed in the modern factory supply us in bulk with this morbid material. Nor is the former gloomy outlook justified to-day, for surgery has not lagged in the race, and injuries contemplated with awe by our predecessors are confronted without misgiving and treated with success by modern methods.

Figures given by older authorities, such as Von Bergmann, Mikulicz, and Bruns, indicate that fractures of the pelvis constitute only 0.3 per cent. of all fractures. From my own experience alone the percentage appears to be greater. To illustrate these lectures I had no difficulty in recalling seven comparatively recent cases, without going through the hospital records. It must not be taken for granted that fractures of the pelvis arise only from severe injuries. Cases have been recorded from a slight fall on the hip, and death has followed in such cases from visceral injury and peritonitis.

In Malgaigne's classical double vertical fracture, the flanges of the ilia are approximated, the anterior portion of the pelvic arch breaks, and posteriorly there is either separation of the sacro-iliac joint or fracture of the ilium vertically downward from the crest to the greater sciatic notch (Fig. 1). The fracture in front is often on one side and the fracture behind on the other. When one side of the pelvis is thus broken away from the rest of the bone it and the attached lower extremity are necessarily connected with the rest of the body only by the soft parts which unite the pelvis to the spinal column and trunk. These soft parts are liable to severe stretching, laceration, and other injuries, which will be mentioned later on. The symphysis pubis or the sacro-iliac joint may be torn asunder, and, in a few cases, separation has occurred both at the symphysis and at the sacro-iliac joint. Separation of all three pelvic joints, not associated with fracture, is an injury the existence of which is doubtful, but I have seen a case with Dr. Gibbon FitzGibbon, Master of the Rotunda, in which there were very wide independent movements of one side of the pelvis upon the other due to laxity of the ligaments of all three joints, with no history of injury and not connected with pregnancy.

Of the isolated fractures of the pelvic bones which do not break the continuity of the pelvic ring, fracture of the acetabulum is the most interesting. I have in Mercer's Hospital at the moment a case of dorsal dislocation of the hip which, owing to a fracture of the posterior rim, slipped out of place after several reductions. The reduction was subsequently made by direct extension and swinging movements and maintained in position by fixed extension in a Thomas splint. This is one of the two common types of fractured acetabulum. The second type is illustrated in the case of a man admitted into Mercer's Hospital in 1909 after a severe injury to the hip. An impacted fracture was diagnosed, but X ray photographs showed the head of the femur driven through the acetabulum into the pelvis.

Fig. 1.



Comminuted fracture of the pelvis. (Spencer and Gask.)

In the first group of cases the fracture of the rim is associated with backward dislocation of the femur, and the symptoms are those of dorsal dislocation with difficulty in maintaining reduction. In the second group the head is forced into the acetabulum, causing fracture; sometimes the head passes through the fracture into the pelvis, sometimes not. The diagnosis is, in consequence, sometimes easy and sometimes difficult. In the more severe type the trochanter is less prominent than normal, the shortening is slight or absent; there is, of course, severe pain, and motion is restricted in every direction.

In differentiating between fracture of the acetabulum and fracture in the region of the neck of the femur, it will be remembered that in fractures of the neck from severe violence the limb lies extended and usually rotated outwards, and that impaction comminutes and makes the trochanter prominent. In fractures of the acetabulum with penetration of the head of the femur, the trochanter is much less prominent, but the difference may not be sufficient to make a diagnosis. In both conditions there is usually absolute loss of function. In most cases help may be obtained by making a rectal examination, but most surgeons will reserve judgment until an X ray photograph has been obtained.

In the one case of central dislocation through the acetabulum into the pelvis which I have seen reduction was impossible, but a fairly good functional result followed. The man, on leaving hospital, was able to continue his occupation as a hackney car driver.

Amongst the seven cases to which I have referred is one of isolated fracture of the sacrum and fracture of the coccyx in a child of 12. She fell from a swing on her sacral region. The interest in this particular case was the absence of symptoms except for some local pain. The patient was brought in casually for examination three weeks after the injury. An X ray

---

* All the cases referred to were illustrated by lantern slides.

photograph showed a transverse fracture of the sacrum between the third and fourth segments without displacement. She was seen four years later and had no pain or trouble of any kind.

When displacement of the fragments occurs the injury is extremely painful and some of the sacral nerves are likely to be involved. There may be also interference with defæcation and urination in some cases due directly to the displacement of the fragments, in other cases to paralysis following injury to the sacral nerves. The displacement of the fragments can be felt per rectum, and under an anæsthetic the alignment can sometimes be restored. Fractures of the sacrum alone are very rare.

Fractures of the coccyx, owing to the mobility of the bones, are also extremely rare, and are of importance owing to the probability of subsequent coccydynia, necessitating removal of the bone. Fractures of the ilium are not uncommon. They involve the upper expanded portion, including the crest, and cases are reported in which the anterior superior, and inferior and posterior spines have been torn away by muscular action. With the body bent forward and the thighs flexed upon the pelvis, there is sufficient muscular relaxation to detect a fracture, and a good X ray picture can be obtained by placing the injured side upon the plate and passing the rays obliquely from before backwards. In treating these fractures care must be taken not to press the fractured portion of the ilium unduly inwards.

Isolated fractures of the ischium are extremely rare. Many standard authorities are silent upon this subject. Bennett[1] described a case in which the ischium was detached from the left innominate bone by fracture with displacement backwards and upwards. The great sciatic notch in this case was reduced to a mere slit, and the displaced bone was united to the side of the sacrum. The head of the femur participated in the displacement.

Treatment.

The treatment of fractured pelvis resolves itself into treatment of the injured soft parts and of the fractured bones.

INJURY TO THE URETHRA, BLADDER, AND SOFT TISSUES.

The urethra and bladder are the organs which suffer most frequently and, as compared with these, injuries to other parts are of little practical importance. The rectum and vagina may be injured, or the large veins of the pelvis may be torn—an accident rapidly followed by death. In a case recorded by Bell and Fischer a diffuse traumatic aneurysm of the gluteal artery developed after fracture of the pelvis. Bryant reported three cases in which thrombosis of the external iliac artery followed a fracture of the pelvis. This was due to over-stretching of the artery by the displaced fragments. The internal and middle coats had been torn, the external coat remained intact. In one of these cases gangrene of the leg developed.

Large extravasations of blood after injury to the pelvis may undergo suppuration. The sciatic and obturator nerve may be crushed, with subsequent prolonged and intractable neuralgia. It is, however, the complication of rupture of the bladder and rupture of the urethra, or of both, which is of most practical importance and requires urgent attention. If such complications are recognised without delay and treated along rational lines, the immediate and ultimate results are not at all so depressing as many would have us believe.

Rupture of the Bladder.

Rupture of the bladder may follow injury apart altogether from fractures of the pelvis, or the rupture may be associated with fracture of the pelvis without being actually produced by the broken bones. The site of the lesion may be either above or below the peritoneal reflection. If below, the tear is on the anterior surface, either in an accessible position or out of reach low down in the neighbourhood of the trigone. If the rupture is intra-peritoneal, it is placed more often on the fundus of the bladder or posteriorly. According to the position, the urine either escapes into the space of Retzius and percolates towards the anterior abdominal wall, or it is freely extravasated into the peritoneal cavity.

In the surgical works of Spencer and Gask, to which I am indebted for much information on the subjects under review, it is stated that wherever stale urine spreads it produces inflammation and sloughing. This statement applies, however, as is made clear in the text, to the more familiar types of extravasation following the ulceration and rupture of the urethra behind an old-standing stricture. The urine under such circumstances is foul and infected. On the other hand, the onset of peritonitis, cellulitis, and suppuration, with accompanying rigors, rise of temperature, and general symptoms of toxæmia, may be delayed for a period of even two or three days in cases of leakage from the urinary bladder containing healthy urine.

I recollect a case which occurred in a casualty clearing station in France, in August, 1916. The patient had fallen from the roof of a house, fractured his jaw and both forearms, and, so far as it was possible to ascertain, had sustained some fracture in the region of the pubes. He had abdominal tenderness, and made ineffectual attempts to pass water. Ruptured bladder was diagnosed, but on passing a catheter a full quantity of urine was withdrawn and it contained blood. The amount withdrawn appeared to us to justify delay. The abdomen became more rigid in a few hours, but his pulse remained between 80 and 90, and there was no vomiting nor rise of temperature. The inability to urinate continued, and a catheter was passed every four hours. Blood was present only on the first occasion, and urine was withdrawn at every catheterisation in moderate quantity. The patient's aspect became gradually worse. Rigidity was more marked, vomiting had commenced, and early signs of peritonitis became evident.

When I operated upon this patient 24 hours after admission a large rent was found on the fundus of the bladder, and the abdomen was full of urine without odour. The rent was stitched and the abdomen closed without drainage. A catheter was passed while the abdomen was still open, and it became obvious that on each occasion the catheter had gone through the rent in the bladder and the urine had been drawn from the peritoneal cavity. The first diagnosis on admission had been correct, but the result of catheterisation was so confusing that there was uncertainty and delay. Notwithstanding the multiple injuries and the lapse of 24 hours before operation, the patient did well.

The diagnosis of ruptured bladder is not as a rule difficult. There is always a strong but ineffectual desire to urinate. A catheter passes freely through the urethra, but only small quantities of blood-stained urine return. To make a diagnosis, some authorities suggest that a measured quantity of fluid should be injected and the quantity returned carefully noted and checked. The disadvantages of such a procedure are obvious. If the injected fluid leaks through a rupture into the peritoneal cavity the desired information is obtained, but the shock from which the patient suffers becomes more pronounced. If it returns in full quantity it may have passed through an extra-peritoneal rupture into the space of Retzius and return without appreciable diminution of quantity. Under such circumstances the surgeon is misled.

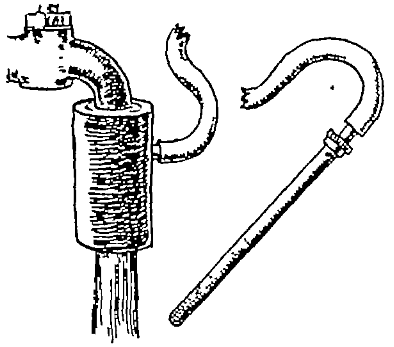
With an inability to void urine, associated with the free passage of a catheter and the return of only small quantities mixed with fresh blood, the case is one for immediate operation. The differential diagnosis between intra- and extra-peritoneal rupture is difficult in the presence of shock, tenderness, and rigidity, but the treatment is the same. Some suggest that the first exploration should be above the pubes, below the peritoneal reflection, but I agree with Keyes, who recommends the peritoneum to be opened in the first instance. The intra-peritoneal rupture is more common, and, furthermore, in dealing with extra-peritoneal injury in the presence of blood and extravasated urine and an empty bladder, sufficient room can scarcely be obtained by the usual extra-peritoneal suprapubic route.

---

[1] Trans. R.A.M. in Ireland, 1887.

If the abdominal cavity is found to contain urine and blood, it is syphoned off through the simple aspirator (Fig. 2) now used largely for the withdrawal of accumulations of fluid of any origin, and the rent in the bladder is closed and covered, *if possible*, by a piece of omentum. A small corrugated rubber drain is passed to the line of suture. A self-retaining rubber catheter is introduced per urethram.

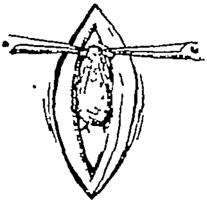
FIG. 2.



Aspirating pump attached to water tap.

In some of the earlier cases described by Walsham death followed operation owing to leakage at the point of suture, and on this account some recommend that fluid should be injected through the urethra to make sure of a water-tight closure while the abdomen is still open. I think such a procedure adds to the time and leads to confusion during operation, and that the use of a self-retaining catheter is a sufficient safeguard. If, on the other hand, it is found that the rupture is not into the peritoneum, the abdominal contents are packed away, and the injury usually will be found on the anterior surface of the bare area of the bladder and should be sutured in the ordinary way. A tongue-shaped portion of omentum (Fig. 3) pulled through the line of peritoneal reflection is laid flat over the surface to secure a firmer union. The space of Retzius is drained and a self-retaining catheter introduced.

FIG. 3.



Opening in bladder covered by omentum.

In certain cases where the rent is inaccessible for accurate suture and where bleeding has been free, suprapubic drainage with a tube in the bladder is the operation of choice.

Rupture of the Urethra.

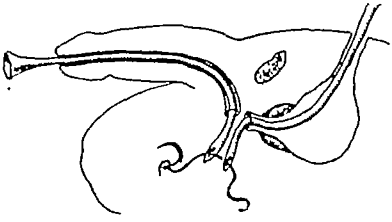
I will give two examples of recent cases of fractured pelvis brought about by a horse rearing and falling backwards on the rider, in which the urethra was ruptured. They illustrate the difficulties of treatment under one set of circumstances and the satisfactory outcome and ease of operation when conditions are favourable.

In the first case the patient, aged about 28, was injured in the manner indicated early in September, 1921. He was seen late at night in the country, after an accident in the early morning. He had been making intense but ineffectual efforts to pass water, and there was consequent extravasation. *It was impossible to pass a catheter beyond the region of the triangular ligament.* Urine and blood were penetrating into the perineum, scrotum, and from the space of Retzius forwards towards the anterior abdominal wall. Both layers of the triangular ligament were apparently torn.

The operation was of the emergency variety. The bladder was opened above the pubis and drained, and free incisions were made into the infiltrated tissues of the perineum. After ten days the patient was brought to Dublin, and an X ray photograph showed a double vertical fracture *involving both rami of the pubes on one side and the region* of the sacro-iliac joint on the other. The acetabulum was involved, a complication which subsequently led to bony ankylosis of the hip. Eleven days after the accident, in the presence of many drainage incisions, a successful attempt at secondary suture of the urethra was performed by a colleague, who kindly took charge of the patient during my unavoidable absence from Dublin.

An operation after such a lapse of time and in the *presence of infection is often very difficult* and unsatisfactory, and is followed usually by traumatic stricture. The hip joint, which was involved by the fracture and open to infection, was exquisitely painful, a condition which added considerably to our difficulties. Extension and abduction were employed until the patient was discharged from hospital five months after admission.

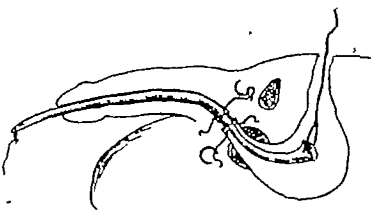
FIG. 4.



Catheters passed and made to point in perineum. (The instrument passed in *retrograde fashion* should be metal.)

I *found it necessary to pass sounds frequently*, generally under an anæsthetic, for nearly two years. Four weeks ago I received the following letter from this patient. He had failed to report regularly for over a year: "Sounds were last passed on me on Oct. 8th, 1923 (two years after the injury), and the last abscess was opened in November, 1923. Since then I have had nothing done, and have been very well indeed. I cannot yet manage to ride, but find every time I try I can manage better. There is a great strain when my legs are across a horse. I play a fair amount of golf and dance a bit, and I have great hopes of riding again some day." From this letter it would appear that the ankylosed hip is the main disability. It is a satisfactory report three and a half years after so serious an injury.

FIG. 5.



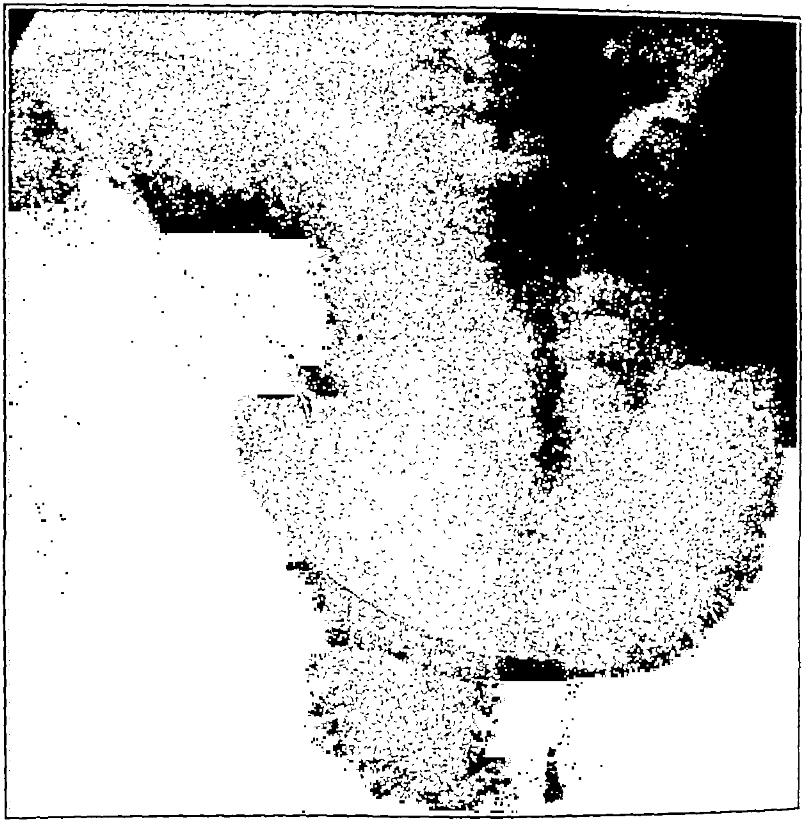
Urethra sutured with catheter as a guide. Note the thread coming through suprapubic wound.

I am indebted to Dr. J. V. O'Hagan for the later history of this case.

The second case arrived in hospital a few hours *after his accident, and illustrates* the happy results which follow when surgical interference is early and when ideal treatment is possible.

A young officer fell with his horse on top of him while hunting. The pubes appeared to be pulled apart, and X rays showed a stellate fracture along one margin of the joint. Again, there were all the signs of urethral rupture—a great but ineffectual desire to urinate, a desire which his medical practitioner in the first instance wisely warned him to curb. Efforts to pass a catheter completely failed.

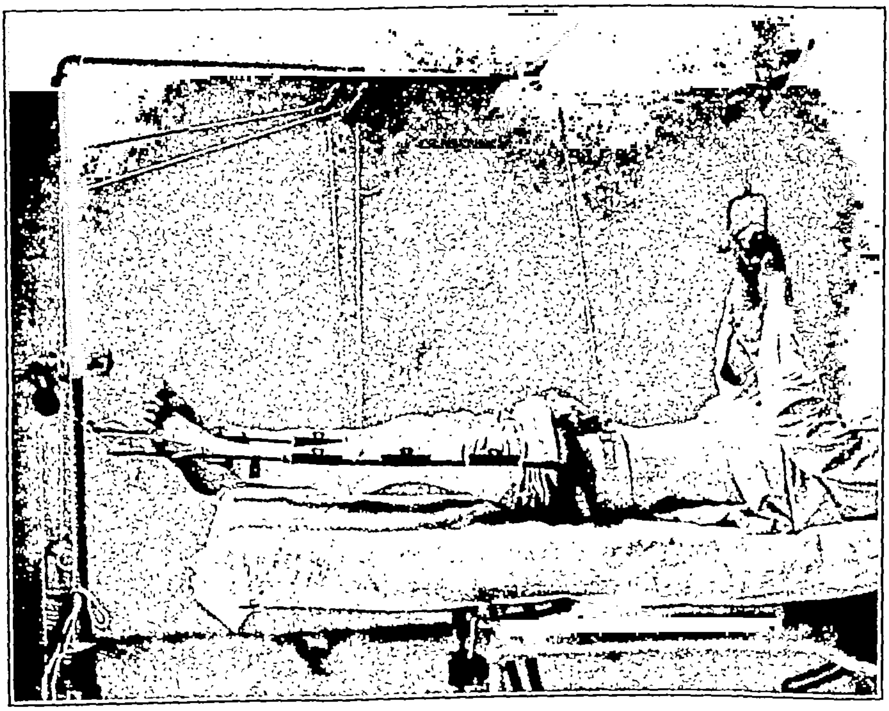
FIG. 6.



Double vertical fracture in which there were no indications of bony injury before radiograph was taken.

The line of treatment adopted is the line I would recommend in cases seen early. Instead of opening up the perineum through infiltrated and bruised tissues in search of the proximal end of the urethra, it is best, I think, to open the bladder in the first instance, and to pass a catheter in retrograde fashion down through the proximal portion of the tear. An assistant holds this instrument while the end of it is exposed through a perineal incision. A rubber catheter is now passed through the penile portion, and the eye is attached by a silk thread to the instrument passing from the bladder. The bladder instrument is withdrawn, pulling with it the rubber catheter, the eye of which now appears through the suprapubic wound. The urethra is then accurately sutured end to end with the rubber catheter as a guide (Figs. 4 and 5). A good headlight is essential for accurate work. The perineal wound is cleansed, preferably with some of the chlorine preparations (such as "Fecto") or treated with bipp. It is then sutured closely, a small superficial rubber drain being left in situ. A long thread is attached to the point of the catheter coming through the suprapubic opening before it is gently manœuvred into the bladder by a pull on the penile end; this thread may be conveniently tied to one of the skin sutures. The bladder is drained by a small suprapubic tube. At the end of four or five days a fresh catheter is attached by a stitch, to the meatal end of the one already in position, and by pulling on the suprapubic thread the new catheter takes the place of the old. This process can be repeated for a fortnight when a catheter is passed in the ordinary manner and the suprapubic wound allowed to close.

FIG. 7.



Convenient arrangement for treatment of pelvic fractures.

The patient so treated was admitted to hospital in January, 1924. He was up and about at the end of five weeks, and left hospital six weeks and two days after admission. On a few occasions afterwards an instrument was passed without difficulty, and he rejoined his regiment apparently well.

Fracture of the Pelvis without Distinctive Signs and no Complications.

The third illustrative case shows a double vertical fracture in a lady who was unfortunate enough to be in a motor-car when it overturned and who had apparently no injury to the soft parts beyond bruising and ecchymosis. At the first examination she stated she felt bruised and sore, and had some pain in her back. Movements of her knees and hip-joints did not cause pain; no shortening could be found. The crests of the ilia were in normal position; pressing them inwards caused no special pain. Rectal examination revealed nothing, and I came to the erroneous conclusion, in agreement with the local doctor, that there was no gross bony injury. An X ray examination was made as part of the routine examination, and a fracture was found on the left side, splitting the ilium from the lower angle of the sacro-iliac joint to about the middle of the crest (Fig. 6). The pubic arch on the right side was broken above and below the obturator foramen. The patient was kept in bed for six weeks, and after two months was able to move about apparently well. This lady wrote to me a few weeks ago as follows: "I am glad to say I feel absolutely no ill-effects in any way. I am not the slightest bit lame, and can dance all night; I have danced four nights this week into the early hours of the morning. I had not ridden for eight years, and rode for the first time recently, and went for a short gallop about a mile, and never felt anything. In fact, I can do anything I ever did before."

With regard to the treatment of fractured pelvis apart from complications. When a double vertical fracture exists, or when the bones are much comminuted, some effort must be made (1) to reduce displacements, (2) to give stability to the fragments, and (3) to assist nursing.

The muscles attached to the broken bones can be relaxed to some extent by flexing the leg at the hip and at the knee (Fig. 7). Both legs should be slung in Thomas splints in this position. (The splints in the illustrations should be shown bent at the knee.) A girth or strong bandage is strapped tightly round the pelvis between the trochanter and the ilium. Strong cords are attached to a ring on each side of the girth (Fig. 8) and passed over pulleys towards the head of the bed, where they are connected to a handle which the patient grasps when changing position. The raising of the pelvis for nursing purposes is thus rendered easy. If one side is displaced upwards, extension is applied to the corresponding leg by weight and pulley. As an alternative the double Thomas frame, as recommended by Jones, leaves little to be desired.

Isolated fractures of the pelvis must be treated intelligently. In the case of fracture of the posterior rim of the acetabulum, the dislocated hip, as already stated, can be easily reduced by direct extension with the patient lying on the floor under an anæsthetic. Extension can be maintained, and recurrence of the dislocation prevented, by the application of a Thomas splint with fixed extension. Cases have been described where a central dislocation of the hip with fracture of the acetabulum have been successfully reduced and treated. No routine manipulation can be described. Ordinary traction in the long axis of the limb and slight abduction may succeed. Lateral traction is indicated, but if the head has perforated the pelvis it will be necessary forcibly to disengage it from the encircling acetabulum before lateral traction will become effective.

In the rare case of fractured ischium, which involves the acetabulum and in which the head of the bone is drawn towards the sacrum, obliterating the sciatic notch, heavy weight and pulley extension seems the obvious remedy.

Patient raised by his own aid for nursing purposes.

SOME OBSERVATIONS ON THE DOSAGE OF ULTRA-VIOLET RAYS IN ARTIFICIAL SUN TREATMENT.

BY ALBERT EIDINOW, M.B., B.S. LOND.,
M.R.C.S. ENG.

(From the National Institute for Medical Research, Mount Vernon, Hampstead.)

THE general method adopted in the treatment of disease by means of heliotherapy or "artificial sunlight" consists of the gradual exposure of the body to a source of light emitting ultra-violet rays. Dr. Leonard Hill has shown, by means of the acetone methylene-blue light gauge, that there is a great variation in the intensity of ultra-violet rays at different times of the day and at different parts of the country. Many kinds of "artificial sun lamps" are being used in various clinics where light treatment has been adopted, all of which vary considerably in their electrical energy and in the ultra-violet energy they radiate. These facts show that it is very difficult to compare or contrast the results obtained at the various clinics, for if patients are exposed to light for a definite period of time the actual quantity of the ultra-violet energy they receive must vary enormously.

The original work of Widmark[1] showed that the ultra-violet rays produced a biological action in the skin. Finsen, Freund, and Hamer carried this research further, and have conclusively proved that the ultra-violet rays which have the power of producing sunburn possess very great therapeutic value. In the practical application of light no isolated portion of the ultra-violet spectrum can be usefully employed, as there are no means available at present to produce individual bands of the ultra-violet spectrum of sufficient intensity.

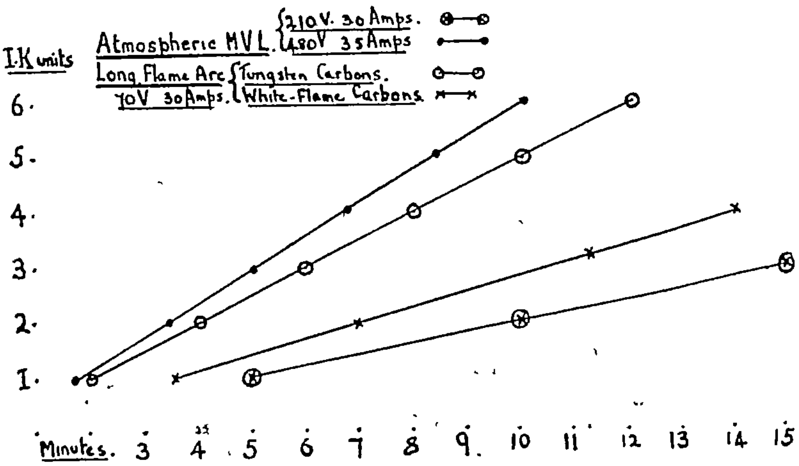
---

[1] Scand. Arch. f. Phys., 1889, i., 264.

Dosage of Ultra-violet Light Sources.

As a result the whole range of the spectrum, including heat, luminous, long and short ultra-violet rays, is employed, and the mass effect of the rays must be considered. Up to the present very little attention has been given to the question of dosage of ultra-violet light sources, and many workers consider this superfluous. The individual variations in sensibility to light make it impossible to fix a standard dose, even with a standard source of light. From this point of view it is indeed very difficult to determine the most suitable method for administration of light treatment, and further to decide if any harmful effects can take place from excessive dosage with light. Two important facts must be considered before accurate dosage with light can be established: (1) The quantity of ultra-violet rays which have biological action, emitted from a source of light; (2) the reaction of the skin to standardised doses of light.

CHART 1.



According to the investigations of Hausser and Vahle,[2] the ultra-violet rays of about 3130–2530 λ have the power of producing erythema of the skin. They exposed small areas of the skin of the arm to isolated ultra-violet rays by means of a large quartz spectroscope. The energy of the rays used was taken of equal value as tested by means of a sensitive thermo-electric couple. These investigators gave the following scale of skin sensibility estimated in relation to the degree of erythema produced:—

Wave length in λ.		Sensibility. Per cent.	Wave length in λ.		Sensibility. Per cent.
3130	.. ..	4·5	2800	.. ..	28
3020	.. ..	58	2650	.. ..	19
2970	.. ..	100	2530	.. ..	16
2890	.. ..	30			

Rays shorter than 2530 λ also produced a faint erythema.

H. v. Schrotter[3] has shown that light from 3600 λ was effective in producing erythema; Leopold Freund[4] claimed that light from 3000 λ was effective; but these observations cannot be confirmed. Therefore, according to Hausser and Vahle's investigations, 69 per cent. of light erythema is caused by 3020–2970 λ. Johansen[5] placed this percentage as 72. Dr. L. Hill has shown that when the skin of the forearm is exposed to light through a quinine filter (which cuts out all rays shorter than 3300 λ) no erythema developed after one hour's exposure. Further, he exposed his arm to the cadmium spark through a quartz spectroscope, and definitely showed that the rays 2750 and 2570 produced erythema, while 2320 and rays shorter than this failed to do so.

These facts clearly demonstrate that dosage of the ultra-violet must be primarily focused on the intensity of the wave-lengths about 3000–2500 λ, since this group of rays correspond to the rays which have biological action on the skin and on the therapeutic value.

Up to the present moment four methods of dosage have been recorded: (1) Bering-Meyer's[6] iodine method is based on the separation of free iodine from an acidified potassium iodide solution by means of light. Hackradt[7] determined the iodine colorimetrically with the Authenrith Konisberger colorimeter. (2) The Eder-Hecht Graukeil photometer was introduced by Freund,[7] and is based on the sensitiveness of silver photographic paper through a graded gelatin wedge. (3) Fürstineau's[8] aktinometer is based on the changes in the electrical conductivity of selenium on exposure to light. (4) P. Keller's[9] modification of the Bering-Meyer's iodine solution. He added starch and varying quantities of sodium thiosulphate to the potassium iodide solution and obtained a blue colour on irradiation. He has biologically standardised this solution against skin erythema.

All these methods, except that of P. Keller, do not bear any definite biological relation to skin erythema. All of them give reaction with the luminous and long ultra-violet rays, and are not specific in their reactions to the erythema-producing rays—shorter than 3000 λ.

The *methods of dosage of light* which have been adopted in the present research consist of: (1) Biological standardisation of sources of light; (2) test of sensitiveness of the skin to light; (3) the effect of a test dose of light on the bactericidal powers of the blood.

The Method Employed in Biological Standardisation of Sources of Ultra-violet Light.

Dr. L. Hill and the writer have shown that when infusoria are placed in a shallow water-cooled quartz cell and exposed to a source of ultra-violet rays they lose their motility and are finally killed. The time taken to produce this action depends upon (1) the distance from the source of light, and this corresponds to the law of inverse squares; (2) the temperature[10]; (3) the intensity of ultra-violet rays shorter than 3000 λ present in the source of light.

The bleaching of a standard solution of acetone methylene-blue corresponds to the action of light on infusoria, but proceeds at a slower rate. The time required to bleach a standard blue solution No. 9 of acetone methylene-blue to No. 8 corresponds to two to three times the time required to kill infusoria under similar conditions on exposure to the mercury-vapour lamp and four to five times that required on exposure to the carbon arc. Recently T. A. Webster prepared a rapid solution of acetone methylene-blue (No. 4), which was completely bleached in the same corresponding time to that taken to kill infusoria. Unfortunately, this solution is of an unstable character. The time taken to bleach a standard solution of acetone methylene-blue and the time taken to kill infusoria, at a temperature of 18°–20° C. and at a distance of 30 inches—i.e., the distance at which patients are usually exposed to light—gives a very satisfactory index to the quantity of ultra-violet rays which have biological action present in a source of light.

[6] Ibid., 1912, i.
[7] Ibid., 1920, x.
[8] Ibid., 1921, xii.; D. med. W., 1920, No. 49.
[9] Strahlentherapie, 1923, xvi., 62.
[10] The biological action is accelerated with a rise in temperature within the biological mean of life of the organisms (5°–30° C.).

If an area of skin is exposed to source of ultra-violet light erythema is produced after a latent period of four to six hours at the site of irradiation. The intensity of erythema corresponds to (1) the distance from the source of light—corresponding to the law of inverse squares; (2) the temperature—the action of the ultra-violet rays is accelerated by temperature; (3) the intensity of ultra-violet rays emitted from the source of light; (4) the susceptibility of the skin to light.

As a general working rule Dr. L. Hill and the writer have shown that an exposure of the normal white skin to a source of ultra-violet light, corresponding to twice the time required to kill infusoria under similar conditions, gives rise to a mild erythema. In this way the reaction of infusoria to light, the reaction of acetone methylene-blue solution, and the erythema of the skin after radiation have been standardised. All sources of light can therefore be standardised by means of these biological, chemical, and skin reactions, and the tests have a relation to each other.

The dose of light can also be expressed in terms of the time required to kill infusoria, each I.K. unit corresponding to the time required to kill infusoria, under the conditions in which the skin is irradiated. Table I. shows the I.K. values for (1) the long flame arc — 30 amps. + 75 volts with white flame carbons; (2) the long flame arc 30 amps. + 75 volts with tungsten carbons; (3) the atmospheric mercury-vapour lamp 200 volts + 3·2 amps. (K.B.B.); (4) the atmospheric mercury-vapour lamp (M.V.L.) 480 volts + 8·5 amps. (See Chart 1.)

Individual Sensitiveness of the Skin to Light.

When three small circular areas of skin, about half an inch in diameter, are exposed to light for three periods of time corresponding to 2, 3, and 4, infusoria killing units on erythema varying in intensity is developed at each area exposed. Individuals vary in their sensibility to these standard doses of light, and besides this, the skin of different parts of the body varies in its sensitiveness to light. As a general routine the abdominal skin one inch above the umbilicus was selected for testing the sensitiveness to light.

A black silk band was attached to the abdomen by means of pieces of tape. This band had three circular diaphragms, about half an inch in diameter, cut out at two inches distance from each other, and had a black silk flap attached, so that each area could be easily covered up. The abdominal skin was exposed over these small areas to the source of light for periods of time corresponding to 2, 3, and 4 I.K. units. The following day two or three circular areas of erythema could be observed at the site of irradiation. The degree of erythema produced was estimated by means of the Lovibond skin colorimeter. Of all the patients tested in this way most gave a reaction with doses corresponding to 3–4 I.K. units, and the degree of reaction was taken as an index of the general individual sensitiveness to light. The colour of a normal white skin usually corresponds to the red No. 1 and yellow 1·0 of the tintometer scale; the exposure to light for 2, 3, and 4 I.K. units gave a very faint erythema with the 2 I.K. dose which disappears rapidly; sometimes it is not visible after 24 hours. The 3 I.K. dose gave an erythema which

was marked and persisted for two to four days. The 4 I.K. dose invariably gave rise to an erythema which was followed by desquamation and pigmentation.

The Lovibond tintometer is a very arbitrary method of estimating the colour of the skin and in many ways it is tedious. Much depends upon the individual selection in comparing colours, and the illumination of the skin plays an important part. It is anticipated that a better and more accurate method of controlling reactions of the skin will be adopted shortly.

The reaction of the skin and the power to produce erythema and pigmentation does not follow the usual routine in infants up to the age of 3 years. The reaction to light in these cases appears to differ from the adult skin. In comparing the erythema produced by varying doses of light, the degree of redness with each dose is obvious and gives a ready means of estimating the sensitiveness of the skin and the reaction to the source of light (Table II.).

Effect of a Minimal Erythema Dose of Light on the Bactericidal Power of the Blood.

Dr. Leonard Colebrook,[11] Dr. L. Hill, and the writer have demonstrated that exposure of the human skin or that of animals (rabbits and pigs) to a source of ultra-violet rays produced an increase in the hæmobactericidal power of the blood. It is therefore possible to observe the effects of radiation of the skin by estimation of the bactericidal power of the blood. Following the results obtained from these observations on the effect of the test doses of light on the abdominal skin, the dose of light most suitable for production of an increase in the bactericidal properties of the blood can be determined. In most of these investigations the dose of light selected was that which gave rise to a mild erythema which persisted for one to two days and then disappeared. This dose usually corresponded to 3 I.K. units. The chest and back exposed to the dose of light selected, after carrying out the test dosage of the abdominal skin, usually showed a very faint erythema of the chest—a mild erythema of the back and a definite line of demarcation at the level of the iliac crest, at the zone between the normal and irradiated skin.

General Plan of Procedure.—Three small areas of the abdominal skin were exposed to the mercury-vapour lamp (480 volts and 3·5 amps.) for 3½, 5, and 7½ minutes respectively, at a distance of 30 inches. This corresponded to 2, 3, and 4 I.K. units. The following day these small areas of erythema of different intensity were observed at the sites of irradiation. By means of the Lovibond skin colorimeter the degree of erythema was estimated for each dose of light and was gauged in the manner shown in Table III.

Yellow	1·0	1·0	1·0	1·0

All these areas irradiated show a definite erythema, although the 2 I.K. dose was faint. The dose of light selected for the bactericidal test was four minutes—i.e., between 2–3 I.K. units. From a series of investigations it has been found that patients who respond fully to all three doses of light, especially the 2 I.K. dose, are very sensitive to radiation. A sample of blood was taken by means of venepuncture and was placed in a sterile test-tube and defibrinated. The back and chest (to the level of the iliac crest) were exposed to two mercury-vapour lamps each 30 inches in front and behind the patient for four minutes. This corresponds to 2½ + 2½ I.K. units = 5 I.K. units. Two and a half hours after radiation a second blood sample was collected and defibrinated in the same way. The bactericidal power of the blood was estimated by means of slide cells, by the method described by Sir A. E. Wright, L. Colebrook, and E. J. Storer.[11] The next day results were recorded as given in Table IV.

Average hæmobactericidal power of blood at 4.30 P.M. (2½ hours after radiation)	= 100
Increase in killing power of blood (2½ hours after radiation)	= 17

From a series of investigations of 125 cases on the effect of radiation on the bactericidal power of the blood, it has been shown that a mild erythema of the skin after radiation is usually associated with an increased bactericidal power. The normal bactericidal power of human blood against the staphylococcus is usually high, and similar results have been experienced when the blood is incubated with different strains of streptococcus and pneumococcus. Sir A. E. Wright and his co-workers attribute the rise in bactericidal power to the greater efficiency of the leucocytes. Radiation of the skin with the ultra rays which have biological action produces some change in the blood causing increased bactericidal function. In many of the cases investigated in which subacute inflammatory changes occurred—i.e., No. 64—and in which there was chronic suppuration (116), the bactericidal power was very high indeed. In these cases the persistent mechanism of defence against the organisms can explain this phenomenon, for if the bactericidal power was low in these cases severe illness would result. In 41 cases in which the bactericidal power of the blood was investigated with test doses of light, 33 cases (80·5 per cent.) showed a definite increase from 2–35 per cent. Seven cases showed no change with radiation, and of these five cases had an initial bactericidal power of 98–99·5 per cent. The two remaining cases (Nos. 95 and 125) are of interest as neither showed any erythema after radiation, and when tested again seven days later with a dose of light-producing erythema they showed a marked increase in bactericidal power. One case of the whole series showed a lowering in bactericidal power. The dose of light employed in these preliminary tests corresponds to the minimal erythema dose as gauged by the test dosage armlet. There, therefore, appears to be a strong correlation between the bactericidal results and the erythema produced.

In carrying out these experiments on the effect of radiation on the bactericidal power of the blood, it was shown that heat rays and mustard poultices increased the hæmobactericidal power of rabbits. The heat had always to be sufficiently severe to produce a marked erythema and damaging of the skin before this phenomenon occurred. Prolonged use of a mustard poultice for one to one and a half hours over a large area of skin (the whole of the abdominal surface of rabbits) was necessary. Dr. Leonard

Remarks.—Case 4: Patch of lupus exposed. Case 6: Yellow skin erythema. Cases 14 and 16: Marked erythema. Case 19: Yellow skin (Japanese) erythema. Case 67: Fair skin, light sensitive erythema. Case 75: No skin reaction. Case 95: No erythema after light dose. Case 106: Very slight skin reaction; sallow complexion. Case 125: No reaction of skin after radiation.

Individual and Regional Sensibility to Light.

There is a very marked difference in the degree of erythema of the skin produced by the same dose of light. Fair-haired people are, as a rule, more sensitive than dark people; but this usually applies to large doses of light and is not very apparent with smaller doses. In carrying out the test dosage of the abdominal skin, a high red index, 1·3 and 1·4, and low yellow index, 1·0, usually signifies sensitiveness to light. The skin bearing a high yellow index of 1·2–1·4 is rarely sensitive to light. The soft thin white skin, which sweats readily and easily bruises, is very often sensitive to radiation. Another easy method of detecting light sensitiveness is by means of transillumination of the air sinuses or of the skin. A very brilliant "red reflex" on ophthalmoscopic examination often signifies sensitiveness to light.

The degree of erythema produced by light varies considerably and this can be roughly classified in the following way: (1) Erythema which is just visible and usually disappears without any apparent sequelæ in one to two days. (2) Erythema which is readily perceptible, followed three to four days later by fine desquamation and results in faint pigmentation. (3) Erythema which shows a violent bluish flush, tender and hot on palpation, with slight œdema and raised hair follicles. This is followed by massive desquamation and results in a deep persistent pigmentation. (4) Erythema causing much pain and resulting in blistering and its sequelæ.

The different areas of the body vary extensively in their sensitiveness to radiation. The inner side of the arm and thighs are the most sensitive. The popliteal space, the side of the chest and back are the other sensitive sites of the body. The skin remaining after desquamation is extremely sensitive to light, and often a small dose of light (2–3 I.K. units) will produce a severe erythema and hæmorrhagic vesicles. The skin should therefore be rested for a while after the period of desquamation. Areas of vitiligo are more sensitive than normal skin; scleroderma is very resistant to radiation and only reacts with very slight erythema.

Dr. L. Colebrook[13] has shown that excessive dosage with light will produce a very marked decrease in the bactericidal power of the blood. The extent the luminous and heat rays take in producing this damage is not yet definitely decided. But in many animal experiments in which rabbits were inoculated so as to produce conditions of septicæmia, excessive dosage with light appeared to hasten death. In all cases of acute infections and in very sick patients, the dosage with light can be carefully controlled by means of the bactericidal test. Prolonged exposure to arc lamps increases the risk of overheating the body by means of the luminous rays. Many light-sensitive patients experience headache, sickness, and dizziness on exposure to light. This is followed by general malaise with or even without the presence of marked skin erythema. It is very difficult to determine whether this sensitiveness is mainly due to the ultra-violet or luminous heat rays. They usually appear to tolerate the mercury-vapour lamp better than the arc lamp.

Light Adaptation and Pigmentation.

Pigmentation and adaptation to light follows after repeated radiation. The nature of the colour of the pigment deposited varies with the source of light. Patients exposed to sunlight and the Finsen arc usually show a deep black-brown pigment. The long flame arc and tungsten carbons give rise to a reddish-brown pigment. The mercury-vapour lamp produces a yellowish-brown pigmentation. Karl Dorno[14] showed after many years' investigation at Davos, that in winter there is considerable heat intensity with minimum ultra-violet energy. In spring there is the greatest heat energy with less increased ultra-violet energy. In the summer there is great heat energy and the maximum ultra-violet energy occurring simultaneously. In the autumn there is great heat energy and a comparatively strongly maintained ultra-violet energy. He therefore concludes that the heat intensity fluctuates very little in the high mountains, but the ultra-violet intensity shows great variation according to the time of day and the time of year. The heat and ultra-violet energy—measured on an arbitrary scale and not in actual energy—are equal to one another on July 15th; the heat at noon on Jan. 15th is ten times as great as the ultra-violet radiation. The autumn sun is double as rich in ultra-violet radiation as the spring sun.

CHART 2.

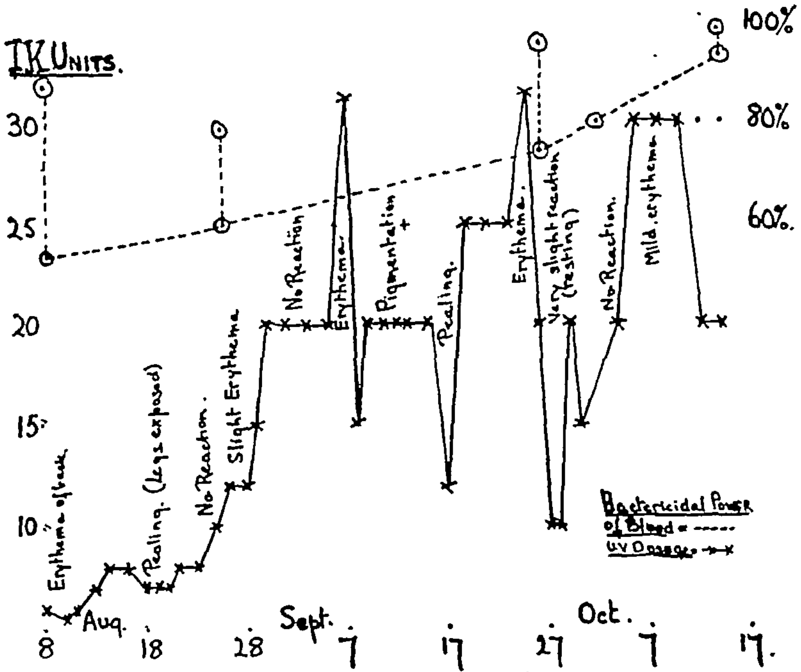

Chart of dosage of U.V. Radiation + Bactericidal power of Blood.

Tubercular Adenitis + Phthisis.—Very yellow skin—mild erythema + much pigmentation c̄ treatment.—

O. Bernhard[15] has shown that marked erythema of the skin occurs in the winter in the glacier regions, and that the most marked pigmentation is seen in the spring. He therefore maintained that pigmentation is prevalent at the time of greatest heat intensity and less increased ultra-violet energy. The chief function of the pigment melanin is to form a protective screen in the skin against excessive penetration of the luminous rays. There is no evidence to support the views of Rollier and Christen—that melanin is an optical sensitiser, similar to eosin and erythrosin.

Pigmentation is an effective screen to the action of the ultra-violet rays and prevents their biological action. Rost[16] has shown that skin areas repeatedly exposed to the Kromayer lamp become insensitive to light independent of the degree of pigmentation. There is no method available at present to determine the degree of pigmentation in any definite units, and therefore it is difficult to draw conclusions on the relation of pigmentation and light protection. Dr. P. Keller has demonstrated the following interesting points: (1) The development of ultra-violet pigmentation is independent of that of tolerance; (2) pigmentation alone does not imply light tolerance; (3) ultra-violet tolerance is possible without pigmentation.

Drs. L. Hill and Argyll Campbell have shown that a suspension of melanin will completely screen the frog's mesentery against the action of the ultra-violet rays and that melanin is not a sensitiser. The fact that pigmentation can be produced apart from light and also by means of heat rays suggests that pigmentation is not specific to the biological action of light. It appears to be closely allied to the heat and luminous rays, since it is more apparent with radiation of the warm sun and the prolonged exposure to arc lamps (one to two hours). The short ultra-violet rays appear to have the power of changing the distribution of the pigment so as to alter the colour of the skin. As the degree of pigmentation increases the sensitiveness to ultra-violet radiation usually diminishes, and light dosage must be increased. As a general working rule an erythema of the skin produced by light gives rise to an increased bactericidal function. It is therefore more advisable to utilise a scheme of dosage which results in the slow production of pigmentation, but definite erythema. This can usually be achieved by utilising a very great intensity of ultra-violet energy, and to avoid overheating of the body by using a short and intense dosage.

The dose of light over the irradiated area is controlled by the degree of erythema produced. During the stages of desquamation the skin is rested, so as to avoid excessive dosage which rapidly results in accustoming to light. A dose of light consisting of 12 I.K. units would correspond to 60 minutes' exposure to the Finsen arc. Seven minutes' exposure to the double M.V.L. (480 volts + 3·5 amps.) + double long flame arc gives a similar ultra-violet energy.

CHART 3.

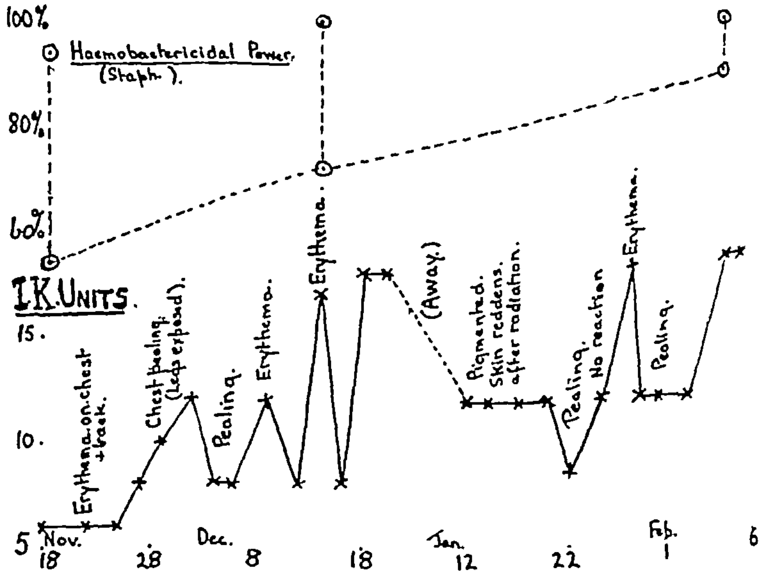

Chart of dosage of U.V. radiation + Bactericidal power of Blood.

Chronic Fibroid Phthisis – Fair Skin – Sensitive to Light – – Pigmented very slightly –

---

[15] Strahlentherapie, 1919, ix., 520.

[16] Deutsche med. Woch, 1918, xxvii.

The amount of heating of the body is, by use of these means, much reduced. In all the cases under observation the degree of pigmentation is slight, and the dosage of light is controlled by the erythema response following radiation. Although it is impossible to decide the issue conclusively, in many cases pigmentation appears to be indicative of therapeutic action of the ultra-violet rays. The reaction of the skin to light, in the production of erythema which in a mild degree appears to be beneficial and in the production of pigment, can be controlled by carefully graded and regulated dosage.

Charts 2 and 3 indicate the dosage of light adopted in a series of cases under investigation. The dose of light is expressed in terms of infusoria-killing units, in the method previously described. In all these cases the light sensitiveness of the skin was first tested and a bactericidal test was carried out, with an estimated erythema dose of light. The chest and back were first exposed to the double mercury-vapour lamps and at each alternate sitting the front or back of the legs were exposed. When the skin became insensitive to 6 I.K. units with the M.V.L., exposure to the double arc was started. This was found to be of great value in the fair-skinned patients, as a very mild superficial pigmentation was present. In all cases exposure to light was stopped during the stages of desquamation, and a sufficient interval of rest was given to allow the newly-formed skin to "harden." The dosage of light was controlled by the reaction of the skin. The aim of dosage was to produce a mild erythema of the skin with each dose applied. In all these cases pigmentation was slight, and the sensitiveness of the skin was maintained during the whole course of treatment. At periodic intervals during the course of treatment, further bactericidal tests were carried out. The general conclusions from the tests showed that in cases where the hæmo-bactericidal power was low, a steady improvement could be established. The erythema dose produced increased bactericidal power in the blood.

SUCCESSFUL RESEARCHES IN THE TREATMENT OF INFANTILE PARALYSIS.

By G. MURRAY LEVICK, M.R.C.S. Eng.,
MEDICAL DIRECTOR, HERITAGE CRAFT SCHOOLS, CHAILEY;
ELECTROLOGIST TO ST. THOMAS'S HOSPITAL, LONDON;
PHYSIOTHERAPIST, VICTORIA HOSPITAL FOR
CHILDREN, CHELSEA.

EXPERIMENTAL treatment of infantile paralysis, carried out recently at the Heritage Craft Schools at Chailey, having been attended with marked success, it seems advisable to publish the results in order that it may be established at other institutions dealing with this affliction of childhood. Improvements will undoubtedly be made in the near future on the methods about to be described; in fact, they are already in mind, but for the reason stated above the writer has been induced to place the work upon record at its present stage.

The cases selected for treatment were, as will be seen below, children some of whose muscles gave no response to the interrupted galvanic current. Moreover, the acute attack resulting in the degeneration of the nerve-fibres had taken place so many years before that, acting on experience gained from the practice of massage and electrical treatment alone, one would have said that further measures with a view to restoring the function of the paralysed part would hardly be justified. At the same time palpation gave the impression that the muscles had not completely atrophied.

These cases having been selected, the treatment was begun on the dates given and has been carried on to the present time. The following measures were adopted:—

1. General radiation of the skin by artificial sunlight. (Occasionally the real sunlight was used, but during the past year this has been so seldom available that nine-tenths of the treatment has been given by artificial means.)

2. Local treatment of the affected muscles by rays from long ray lamps passed through red filters.

3. *Electrical treatment.*

4. Re-education of voluntary stimulus.

5. Instrumental support for the paralysed muscles and then (most important) abandonment of support, in some cases at an early stage. The writer would call particular attention to this matter which is referred to in detail below.

6. Massage.

The deductions which led to the adoption of the above methods of treatment are simply explained as follows:—

General Application of Artificial Sunlight.

Several years ago the writer began to treat rickets in children by means of artificial sunlight. Observation showed that children suffering from active rickets were frequently also suffering from acute neurasthenia. The active symptoms of rickets cleared up very quickly under the administration of the light, but the neurasthenic symptoms were the first to disappear. The deduction drawn from these observations was that neurasthenia and rickets are sometimes causal relatives. Rickets is caused by light starvation, so is neurasthenia. The writer believes that neurasthenia in the adult is a symptom frequently due to the lack of antirachitic substance at a time of life when the complete formation of the bone renders the bony symptoms impossible.

Following these observations he has successfully treated many cases of neurasthenia in adults by artificial light. Thus the disturbance of nutrition in the nerve-centres due to lack of antirachitic substance may be the cause of neurasthenia, and the cure found in the general treatment of the body by light. This would mean that the matter formed by the action of sunlight on the skin is a factor in the nutrition of the nerve-centres as well as of the bones.

With these observations clearly in mind, the writer turned his attention to the treatment of infantile paralysis. This acute infection produces a severe shock upon the whole nervous system. The hæmorrhagic myelitis leads to the total destruction of a smaller or larger number of motor nerve-cells, while at the same time many suffer a temporary suspension of their activities by disturbance of their nutrition in a varying degree, owing to compression. Thus some may recover function in a few days or weeks, others may lie sick and dormant for a longer period, and may lose their axons, which subsequently regenerate following revitalisation of the cell centre. After these attacks we also notice symptoms in the patient that are probably produced by neurasthenia.

Now the muscular atrophy following an acute attack of anterior poliomyelitis is intense, and in those cases where extensive degeneration of the axons has taken place, and has been followed by regeneration, the young axons, when at last they enter their muscular destination, find fibres in such an extreme state of atrophy that no response to the motor stimulus is obtained from them. The atrophied muscle-fibres are shrivelled up, the skeletal elements have lost their elasticity, and the contractile substance appears to have been largely absorbed, so that the nuclei have come together in heaps.

Under the action of light, changes take place in the skin resulting in the formation of the substance mentioned above which is carried away by the lymph and distributed throughout the body by the blood. This we may call the antirachitic substance. It has an intensely active rôle in the promotion of nutrition. Its absence produces the rachitic condition in the bones of growing children and neurasthenia due to the exhaustion of the nerve-centres, while its production by the action of light on the skin results in the re-composition of the rickety bones and the re-nutrition of the nerve-centres.

General Radiation.

So the writer started to treat his paralysed patients by the general application of natural and artificial sunlight to their skins, thinking that of all illnesses there is none so urgently demanding this treatment as acute anterior poliomyelitis. This treatment was given strictly in accordance with the principles laid down by Rollier for treatment by real sunlight, the chief of these being the avoidance of excessive or widespread erythema and a dosage regulated to the tolerance of each individual patient. This artificial light has been produced by the combination of the mercury-vapour lamp and a battery of the long-ray lamp bearing the writer's name, with the red screens in operation.

Having carried out treatment on a very large number of patients suffering from a variety of complaints, with different open arc lamps, the writer now feels confident of the complete superiority of this combination of mercury-vapour and incandescent filament lamps over the open arc lamps. The dosage of the patient with ultra-violet rays can be regulated with much greater accuracy with the mercury-vapour lamp than with any of the open arcs, while the treatment of the patients in the recumbent position is much simpler and better.

It will be seen that the efficient reflexion of the rays from the parabola of the writer's lamp is a most important factor when the shallow penetration of the ultra-violet rays is borne in mind, as the parallel rays from the parabolic reflector striking the skin (as nearly as can be arranged) at right angles penetrate more deeply than the majority of the rays coming directly from the source of the light because most of these rays penetrate the skin in an oblique direction and are consequently arrested nearer the surface.

The reflected rays being therefore of greater importance than the direct rays the advantage of the removable reflector fitted to this mercury-vapour lamp is manifest, as only the daily removal of the reflector for polishing can ensure efficiency of reflection. A nickel surface may be used, and in polishing this, extreme care must be taken that it is not scratched, because scratches particularly impair the reflection of the ultra-violet rays.

In regulating the dosage of ultra-violet light it is well to avoid over-pigmentation of the skin, as a dense pigmentation checks the penetration of the red rays. The writer aims at a moderate pigmentation. Here again most of the open arc lamps are at fault as they produce excessive pigmentation in some patients. This pigmentation is a needed protection when only real sunlight is used, because the proportion of heat and visible rays in sunlight is such that people exposed to them for long periods need something to moderate these waves. When artificial light is used this should not be necessary, and if penetration by red rays is required it is an impediment.

Rollier, supported by Gauvain, has pointed out to us that patients who pigment deeply under sunlight treatment respond better to the treatment than those who do not pigment. The writer is inclined to believe that this observation need not be interpreted as meaning that the pigment itself is the curative factor. It has been shown that the phenomenon of pigmentation is connected with certain endocrines—e.g., pituitrin. It is therefore possible that the "non-pigmenter" does not react to treatment simply because his endocrine production is abnormal, and not because he lacks pigment.

Local Treatment by Red Rays.

The long-ray lamps already alluded to consist primarily of a carbon filament in vacuo, the bulb of which is made of glass. These lamps are specially constructed for the writer by makers of electric filament lamps, as it was found that they were unobtainable. They yield a light much richer in red and infra-red frequencies than the metal filaments in gas-filled globes made for lighting purposes, and the writer was anxious to obtain red rays for the local treatment of the muscles.

The red rays penetrate the tissues much more deeply than the heat rays, because the latter are absorbed by water. The depth of their penetration is demonstrated by the simple experiment of holding the hand in the path of a sunbeam entering a room through a window. The red light will be seen plainly to penetrate the fingers. In order to give a strong dose of red light screens of red glass are fitted to the lamps. These screens cut off enough of the heat rays to enable a much stronger dose of red light to be given to the patient than would be possible without the screens. The red rays themselves produce heat but to a lesser degree than the infra-red.

The writer has found these red rays of the greatest value in the treatment of atrophied tissue and, judging by the results obtained in treating tissues exhibiting chronic inflammation, he has concluded that they produce in these tissues an increased power of resistance and repair, and it is perhaps not unlikely this effect is obtained through the local stimulation of the sympathetic nerve-fibres. There is certainly no comparison between this therapeutic effect of rays from the filament lamps that have been passed through the red screens and the same rays unfiltered, when in each case the dosage of light has been the maximum compatible with comfort and safety for the skin.

In the treatment of rheumatoid arthritis by artificial light the redevelopment of the wasted muscles became very marked when the writer began to use intense red rays. The above observations led to the adoption of this red ray treatment for muscles affected by acute anterior poliomyelitis, and the results given below surely prove its value. From 20 minutes to half an hour daily exposure was given locally to each affected group of muscles, the rays from the mercury arc being given to the body generally as a separate treatment. The writer believes that the time allowed for the local treatment of the paralysed muscles by the red rays might well be increased beyond the limits stated above.

Electrical Treatment.

The rationale of electrical treatment in infantile paralysis has been fully described by the writer in a paper read before the British Orthopædic Association in October, 1922, and subsequently published in the *Journal of Bone and Joint Surgery* of April, 1923, where it is pointed out that in considering the re-nutrition of muscles there is an important point that has always been overlooked and is essential to the restoration of contractility. It is explained by the theory of muscle contraction given by Schaffer.

When a muscle contracts, the clear contractile substance passes into the tubules of the sarcous element, which are elastic and are dilated by its entry. When the muscle is relaxed, this substance flows out of and remains outside the sarcous element, the little tubes narrowing as they elongate. As long as the muscle remains in a state of complete relaxation—for example, when elongated during paralysis—the little tubes remain in this posture. It appears to the writer that the atrophy following the paralysis besides causing absorption of the contractile substance is accompanied by a loss of elasticity in the sarcous element, so that the tubes can no longer dilate to their proper extent to admit the contractile substance for the contraction of the muscle in response to a stimulus. This loss of elasticity may be partial, leading to an impairment of contractility in the muscle, or if allowed to progress far enough, such rigidity is the result that dilatation is impossible and contractility is altogether lost. The above theory is absolutely in accordance with observed facts, and it will be seen that it is a separate condition apart from the mere loss of contractile substance.

In lesions of the lower neurone these changes take place more rapidly in young children than in older children and adults, so that in their case it is very needful to begin treatment early. But in any case there is really only one way absolutely to safeguard these paralysed muscles from this dire catastrophe—that is, to ensure a periodical contraction during paralysis, and the only way to ensure this is to employ electrical stimulation. There are no other means. The greatest care must be taken, however, not to over-exercise the paretic muscle. This is a very important point. A dozen good contractions daily for each muscle are sufficient in the early stages.

The cause of failure of electrical treatment in infantile paralysis lies too commonly in ineffective methods of application, and this leads to erroneous opinions held on the subject by those who observe the results. Treatment directed to an increase of the circulation in the affected limb yields good results up to a certain point, and undoubtedly improvement of nutrition in the limb as a whole takes place when, for instance, it is periodically immersed in a faradic or sinusoidal bath, but as a measure for preserving or restoring contractility of paretic muscles it fails because muscles most affected, and therefore most in need of the treatment, either do not respond to faradic at all, or at the best but feebly, while the normal muscles contract strongly and may do actual harm by stretching their weaker neighbours. This latter evil can be avoided by splintage during the treatment, but this is a difficult matter when a bath is used and a precaution rarely carried out.

It has already been stated that wasting and loss of contractility proceed more rapidly in young children than in older patients. This renders effective treatment the more urgent in their case, especially as the limb will be increasing in length. It cannot be too strongly urged that paralytic muscles should be treated only by operators who have learned this particular work under proper supervision in a school dominated by orthopædic ideas.

Re-education.

Re-education was very carefully carried out. It is most important that the patients should not be exhausted and discouraged by exhortation to contract muscles that will not and cannot respond. Patience should therefore be exercised and re-education withheld until the proper time has arrived, and it should then only be gradually and intelligently carried out. For instance, the long extensors of the toes must not be used instead of tibialis anticus in dorsiflexing the foot.

Instrumental Support.

Instrumental support was considered from an entirely new standpoint, as the writer believes that although it is of paramount importance properly to relieve a paralysed muscle of all tension until voluntary response is restored, yet it is a form of treatment very much overdone. When voluntary response is regained support must be discarded at times altogether, these periods varying according to the state of the neuro-muscular combination at the time being.

There are two points the writer would like to make particularly clear as they are taken into constant consideration, and he regards them as essential. The first of them is that so long as a paretic and wasted muscle is inactivated by a supporting appliance it will rarely regain useful activity, and it will rarely regain sufficient tone owing to the effect of such fixation upon the factors concerned in its production.

The second point is that whereas the constant pressure of the enveloping band or strap of a surgical appliance will cause severe wasting in even a normal muscle, such a factor has a far more serious effect upon a paretic muscle, and should never be allowed. Thus, when the quadriceps muscles are affected in anterior poliomyelitis and a walking calliper is used, flexion of the knee-joint should be prevented by a band passing over the front of the knee only, the straps commonly used, which pass over the quadriceps muscles, being very harmful.

When voluntary response has been regained in the quadriceps the writer has, with certain exceptions, discarded the calliper altogether, believing this to be the best procedure, so long as the psoas and glutei were activating, and allowed the patient to get about with poles or crutches according to the necessities of the moment. In such cases it is easy in this way to let the patient get about without support for the quadriceps muscles if a little care is exercised. The anterior tibial muscles, however, present a more difficult problem, owing to the tendency of the foot to drop into the equinus position during the day (so that some supporting appliance is needed), and to be forced into this position at night by the weight of the bedclothes. Thus a night shoe (keeping the foot at right angles with the leg with slight inversion) should be worn to a late stage, and the masseuse should constantly correct any tendency to shortening of the calf muscles. Should this condition be present in a marked degree when treatment is first begun, much valuable time will undoubtedly be saved by a tenotomy of the tendo Achillis, as in the writer's experience it is impossible permanently to reduce an advanced contraction of the calf muscles by physical means alone.

Before leaving the subject of supports, let it here be said that enveloping plaster-of-Paris splints were never used as these encourage atrophy by depriving the part of all light and air.

Massage.

Massage was carried out as a part of the treatment. In cases where atrophy is advanced it is of use, yet the more the writer uses sun rays, real and artificial, in treatment, the less he is inclined to employ massage. He always has in mind the danger of pulling the inert muscles out of shape in this form of treatment done day after day. This remark more especially applies to deep effleurage which is, in his opinion, a grave mistake. Massage is chiefly needed in cold weather.

Clinical Records.

F. T., aged 13, had an acute attack of anterior poliomyelitis when aged 14 months. Treatment was begun in January, 1924. He had then no faradic or voluntary response in the right quadriceps muscles. On Jan. 28th, 1925, he had regained a good voluntary response in these muscles, varying a little from day to day, but at times he can hold the leg with the knee extended with his thigh in a horizontal position. He is still steadily improving.

J. C., aged 12, had an acute attack of poliomyelitis in early infancy. In February, 1924, the glutei and all muscles of the right lower limb excepting the adductors gave no faradic or voluntary response. Treatment was started on that date. On Jan. 28th, 1925, there was a plain voluntary response in the quadriceps, the response being, however, weak. The glutei gave a good voluntary response, and they are becoming quite strong so as to give really useful activity. The hamstrings have recovered sufficiently to flex the knee-joint through the right angle with the patient lying in the prone position. The peronei have a weak but distinct voluntary response; the tibialis anticus is beginning to give voluntary response; all these muscles are improving.

W. B., aged 11, had an acute attack of poliomyelitis in both lower limbs when 4 years old. In January, 1924, there was no response in the left quadriceps. On Jan. 28th, 1925, these muscles have a weak response almost but not quite strong enough to support the weight of the leg in the horizontal position. The left anterior tibial group were very weak, but are now recovering rapidly; it is to be expected that at the present rate of progress this boy will be able to discard his instrument altogether. In the right leg in February, 1924, tibialis anticus gave no faradic or voluntary response. On Jan. 28th, 1925, it now gives a really useful voluntary response, almost sufficient to dorsiflex the foot. In this case there had been considerable contraction of the calf muscles on both sides so that he had been earmarked for tenotomy. The muscles have, however, completely yielded to manipulation so that the foot can now be placed at a right angle. The remarkable feature of this case is the splendid nutrition of both legs, which have developed excellently in this respect.

T. W., aged 15, had infantile paralysis when less than a year old. On Feb. 26th, 1924, no faradic or voluntary response was obtained in the anterior tibial group or the quadriceps muscles on the right side. On Jan. 28th, 1925, the quadriceps and all the muscles of the anterior tibial group were beginning to give a voluntary response. Atrophy in this case had been very severe, but he has lately much improved. On the left side tibialis anticus gave no faradic or voluntary response at first, but is now giving voluntary response.

Conclusions.

It is, of course, necessary that treatment of such cases as these should be continued over a long period in order to obtain a useful result, that is to say, to establish activation in the paralysed muscles so that they can assume their proper rôle without the support of any appliance.

When we consider that ten years is not thought too long a period for the mental tuition of these children during the greater part of every day, it is surely a very reasonable thing to demand treatment for three-quarters of an hour or so daily for three or four years, because this can very easily be done in establishments especially devoted to the welfare of cripples where they are resident and always available when required for treatment. The above cases have been selected for inclusion in this paper because they have shown a recovery of muscles that were completely paralysed at the beginning of the treatment and are therefore the strongest possible proof of the value of the methods adopted, but while their treatment has proceeded other patients have been treated in the same way, whose muscles were activating very weakly at the beginning of treatment and have shown quite exceptional recovery.

The writer has treated a very large number of cases of infantile paralysis at different hospitals for some years past by the methods mentioned above, excepting the general light treatment and the local treatment of the muscles by the red rays, and he has never obtained results that can be compared with these just described, nor has he seen such results elsewhere. The treatment by light therefore stands out very distinctly as a great advance. Among the cases hitherto regarded as hopeless there are unquestionably a large number in which destruction of innervation renders recovery impossible, and treatment is, of course, thrown away on these. At the same time, examination and a short course of treatment will show whether useful recovery of nerve-fibres has taken place.

Much skill, perseverance, and judgment are required on the part of the operators. The writer must therefore pay a tribute to his assistants, Miss F. Rolleston and Miss I. Seldon, who have been responsible for the carrying out of the above methods.

RHEUMATIC INFECTION IN CHILDHOOD.

BY VINCENT COATES, *M.C.*, M.A., M.D. CAMB.,
PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH ;
PHYSICIAN TO OUT-PATIENTS, ROYAL HOSPITAL FOR
SICK CHILDREN AND WOMEN, BRISTOL, ETC. ;

AND

R. E. THOMAS, M.D., B.S. LOND., D.P.H. BRISTOL,
DEPUTY MEDICAL OFFICER OF HEALTH, AND DEPUTY
SCHOOL MEDICAL OFFICER, BATH.

FIFTY cases, picked at random from a much larger series of Bath school-children selected during routine school inspection and clinic work, either because of heart disease. suspect heart disease, or symptoms suggesting rheumatic infection, have been examined, and 44 in whom the diagnosis was established to the clinical exclusion of other toxic states are reported upon fully. The detail embarked upon negatived the possibility of investigating a larger series. School medical records since 1920, compiled by one of us, were available, and each case in the present series was seen more than once in consultation. The inquiry into home conditions and house inspection was made by voluntary school-care visitors under the direction of the Care Secretary, Miss E. G. Greenall, and the reports were according to a very detailed schedule.

The subject is discussed from the viewpoint of the soil, including inheritance, family history, past history and physical make up of the child, and environment ; and the infection, including subjective symptoms, duration of ill-health, and objective physical signs.

In Respect of the Soil.

Inheritance.—Of the 44 cases diagnosed as suffering from rheumatic infection 21 had an adjacent and 14 a remote family history. By adjacent is meant definite rheumatic fever or rheumatic chorea in either parent, brother, or sister. By remote is meant " rheumatism " in the above relations, or rheumatic fever in a grandparent, uncle, aunt, or first-cousin.

Family Colouring.—The colour of the hair in the above adjacent relations was nondescript in 10, definitely fair in 10, definitely dark in 9, definitely red in 6.

Colour of hair in the cases under review was nondescript in 23, definitely fair in 13, definitely dark in 2, definitely red in 6.

Past history of the same cases : Rheumatic fever in 6, chorea in 11, scarlet fever in 5.

Environment.—Altitude of house : Under 100 ft. in 27 (61·3 per cent.) instances, under 200 ft. in 40 (90·9 per cent.) instances. In only 6 instances was residence in the present house under 3 years—in the remaining 38 cases the residence had been unchanged for over 5 years.

Subsoil.—Alluvial, 13 ; gravel, 15 ; lias, 12 ; other types, 4. The gravel in the majority of these cases is in an area adjacent to the river-bed and used to be flooded.

House Reports.—Damp, 20 ; ventilation inadequate, 14 ; light poor, 12. The terms dampness, inadequate ventilation, and poor light are those which would be, and in point of fact were, applied to conditions striking an ordinary educated person and not a sanitary inspector. In only 6 instances could the term overcrowding be applied to relation between the number of inmates and available rooms. Six houses only had under 4 rooms, 16 houses had 4 rooms, 9 houses had 5, and 13 had 6 or more.

The weekly gross income per head is as follows : In no case was it less than 5*s.* ; in 21 cases it was between 5*s.* and 7*s.* ; in the remainder it was over 7*s.* In practically every instance the parents of the affected children were in steady work, in receipt of a steady income, and generally belonged to the skilled artisan section of society.

In Respect of the Infection.

A history of symptoms in the children was given as follows : Headache in 10, sore-throat in 12, stomach-ache in 26, stiff neck in 8, growing pains in 31, stitch in 20, swollen joints in 3.

The nervous symptoms in the children were : Irritability in 5, nervousness in 14, sleep disturbances in 20, those of chorea in 4.

The duration of symptoms in the children was : Less than 1 year, 10 ; 1 to 2 years, 11 ; 2 to 5 years, 17 ; more than 5 years, 4 ; unknown, 2.

Physical Signs.—Pallor and anæmia are not recorded in that blood counts were not undertaken. In 16 cases the condition of the tonsils was such as to cause chronic enlargement of the submaxillary tonsillar gland.

The cardiac condition in the children was : Morbus cordis in 14, suspect cardiac disease in 22, normal cardiac state in 8.

Subcutaneous nodules were present in 35 children, chorea was present in 6.

The following table explains the association of the principal physical signs :—

Rheumatic infection—	
Without physical signs	5
+ nodules	3
+ chorea	0
+ nodules + chorea	0
+ C.I. (*a*)	0
,, (*b*)	3
+ nodules + C.I. (*a*)	16
,, ,, (*b*)	11
+ chorea + C.I. (*a*)	1
,, ,, (*b*)	0
+ nodules + chorea + C.I. (*a*)	5
,, ,, (*b*)	0

C.I. = Cardiac involvement. (*a*) = Suspect ; (*b*) = Organic.

Examination of Controls for Subcutaneous Nodules.—At routine school medical inspection among the first 100 children examined 25 were found to have nodules, 20 of whom gave a definite history of symptoms suggesting rheumatic infection, 2 an indefinite history, and 3 no history. These children were of the entrant and intermediate groups and accompanied by their parents.

Commentary.

Several salient points emerge touching environment and infection.

In Respect of Environment:—

(a) *Altitude and subsoil*: The figures are remarkable and require no comment. It is to be noted that the altitudes in Bath vary between under 100 feet to over 500 feet.

(b) *Social position of the parents*: Is not one of extreme poverty and slum dwelling, but that pertaining to a more or less skilled worker in constant employment. This directly opposes the suggestion that rheumatic infection is a poverty disease.

(c) The family inheritance and predisposition is confirmed.

In Respect of Infection:—

(a) *Nervous symptoms*: The frequency in which the parents' sole complaint was that the child was nervous and irritable, or was a sleep-talker and sleep-walker, or that there was a combination of these symptoms is remarkable. Seeing that efficient anti-rheumatic treatment cured these conditions it would appear that they are manifestations of the rheumatic virus.

(b) Subcutaneous nodules: As a physical sign the subcutaneous fibrous nodule is a small and apparently insignificant variation from the normal, in consequence of which practice is necessary for the clinician to be certain of its presence. The final proof that such nodules exist rests on their removal and microscopical section.

To quote from Prof. I. Walker Hall's report[1]:—

> "The nodule is composed of fibrillar tissue, aggregations of histiocytes and inflamed blood-vessels. . . . It is obvious that the ætiology of the nodule may be associated with a persistent irritant of the sub-infective or mildly infective type."

This particular reaction to infection, proliferation of the lining endothelial cells of arterioles and perivascular collections of histiocytes, is such as obtains in response to the virus of rheumatic fever, both in the endocardium and pericardium. It would appear therefore not improbable that these nodules are but pocket editions of the large subcutaneous nodes occurring in acute rheumatic fever and are analogous to the submiliary nodules of Aschoff.

(c) Treatment: It has been found that satisfactory results are more easily obtained by the exhibition of small doses of thyroid or iodine in addition to salicylates, alkalis, and arsenic. This treatment was adopted on the presumption that smouldering infections tax the thyroid gland. Rest, exclusion from school, and avoidance of wet were enforced where necessary.

Summary.

Forty-four cases of rheumatic infection in children have been investigated. The opinions reached are:

1. Rheumatic infection in elementary school-children is not a poverty disease.

2. It is extremely prevalent among such children.

3. The potency of heredity and low-lying locality is emphasised.

4. Subcutaneous nodules have been demonstrated in 35 out of 44 cases (79·5 per cent.), and are significant of an active rheumatic focus, as shown by their association with symptoms and their absence in three cases of stationary mechanical carditis formerly rheumatic. Thus their presence not only crystallises an otherwise nebulous diagnosis, but indicates the necessity of continuation of treatment, particularly in nervous children and in those with unsatisfactory cardiac sounds.

We wish to thank Miss Greenall and the voluntary care visitors under her supervision for their most valuable reports and scrupulous attention to detail, without which this investigation could not have been made.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF MEDICINE.

WEDNESDAY, JULY 22ND.

Lord Dawson, President of the Section, in his inaugural address referred to the especial importance of the 1925 meeting of the Association. There were, he said, three things that made it notable—the meeting coincided with the important outcome of recent research into malignant disease; it was held at a time when the duties of the Association were rapidly widening, especially as they affected facilities for learning and teaching and promoted generally the health of the public; and it was held at Bath, which for so long a time had been a leading health centre of the country. Referring further to cancer research, he pointed out that the specificity of the factor of the soil, as opposed to the non-specificity of the virus, illustrated once again the principle that the reaction of man to morbid processes bears upon it the stamp of his own individuality. Modern medicine was opening out the questions of trend and tendency, and as a result medical men of the future must increasingly be the prophets and not the vassals of statesmen. The President then referred with great respect to the late Sir Clifford Allbutt, both as a great thinker and a great leader, and especially as a leader to the B.M.A. during the years of the war. He reviewed his great knowledge, broad outlook, and fine scholarship, and, most important of all, his sane optimism, which had made him pre-eminently an object of the allegiance which age might command in the young.

Sir Humphry Rolleston, after reference to the remarks of the President upon cancer research, and having paid further tribute to the memory of Sir Clifford Allbutt, opened the discussion on

Rheumatoid Arthritis.

He submitted that it was generally felt that the disease, if not entirely due to some form of infection, was, at any rate, chiefly due to it. Was, however, infection the sole cause? Might, for instance, disordered metabolism initiate the changes that occurred in the joints? Such an authority as Sir A. Garrod had expressed the belief that the infective factor had been over-emphasised, and it was necessary to ask whether we were justified in ascribing the arthritis in all cases to infection. Reviewing other possible causative factors, he did not believe that heredity disposition was of much importance. Errors in carbohydrate metabolism had been thought to have a place in the causation of the disease, and it had been reported that 20 per cent. of cases showed a lowered basal metabolism and a diminished sugar-tolerance; these findings, however, probably represented effects rather than causes of the disease, and it had been found that after removal of a septic focus the sugar-tolerance returned to normal; moreover, diabetes mellitus was not commonly associated with rheumatoid arthritis. Similarly chronic infection was more probably the cause of thyroid insufficiency and other endocrine disturbances than vice versa, and on the whole there was not much evidence that such metabolic disturbances stood in causal relationship to the disease.

Speaking of the source of infection, Sir Humphry Rolleston said that in one series the teeth and gums had been found in 90 per cent. of cases to be the main source; in another series the tonsils were infected in 75 per cent. Accessory nasal sinusitis, he thought, might be secondary to dental infection. Two varieties of dental infection had to be distinguished. *First*, pyorrhœa alveolaris, where the infection was open and probably had not much causal effect in arthritis apart from achlorhydria; *secondly*, dental apical abscesses, from which absorption into the blood-stream was direct. In the former mode of infection it was possible that perversion of the functions of the liver, which stood between the alimentary canal and the systemic circulation, might be a contributory cause of the disease; in such cases also the small rather than the large intestine appeared to act as a source of infection. In the genito-urinary tract the *B. coli* might act as an infective agent in a few cases, especially when harboured in the prostate. The respiratory tract, apart from cases of pulmonary arthropathy, could for practical purposes be exonerated. Although the opinion held in France that some cases of rheumatoid arthritis might be due to the toxins of the tubercle bacillus found little or no support in England, yet it was worth bearing in mind a possible analogy between syphilis and parasyphilitic disease on the one hand and tuberculosis and rheumatoid arthritis on the other. He referred also to the occasional association of arthritis with psoriasis and impetigo, and suggested that an anaphylactic relationship might exist between them. The chief objections to the infective theory were that people often have infective foci but no arthritis, and that in many cases we can find no infective focus. The uncertain factor of the soil, however, was to be borne in mind in weighing such objections, and search for a possible focus—e.g., in the prostate or nasal sinuses—was often incomplete. Again, certain foci of infection might be "closed"—the gall-bladder, for example—or one joint might act as a reservoir of infection for other joints. From the bacteriological standpoint it was usually a streptococcus that was incriminated, but there was often difficulty in recovering the organism from the synovial fluid and membranes.

---

[1] Brit. Med. Jour., 1925, i., 530.

As to treatment, prevention was the keynote. Eradication of infection, as, for instance, in dental extraction, must be complete. Just as a match was as effective as a torch in firing a train of gunpowder, so a small focus of infection might set up an arthritis as severe as a large one. Dead teeth were a favourite seat for infecting organisms, and there was consequently a danger in killing the nerves of teeth. As to encouraging the soil, he referred to the possibility of stimulating metabolism by thyroid extract, parathyroid, arsenic, iodine, and heliotherapy, and he drew attention to the theoretical uses of protein shock in therapy.

Mr. W. R. Ackland considered the division of dental sepsis into pyorrhœa and dental abscesses too hard and fast. Apical abscesses sometimes discharged through the gum, while in pyorrhœa, on the other hand the deeper layers could never be properly drained. Gastric juice did not always destroy the streptococcus and it might even liberate an endotoxin. Moreover, there was no gastric juice in the stomach at night, when toxins might pour down into the stomach and ultimately produce achlorhydria, and if the liver functions were affected the infection would pass to the general circulation. The streptococcus appeared to have an especial affinity for a dead tooth. The results of treatment were, on the whole, disappointing. One might at least hope, however, that patients would not get worse thereafter. X rays of the teeth not being infallible, he was in the habit of condemning all bridges, crowns, and dead teeth.

Dr. Rupert Waterhouse, from a hydrotherapeutic standpoint, said that though the infective hypothesis of rheumatoid arthritis was in full swing in Bath 25 years ago, there yet seemed as a result to be no diminution in the number of patients seeking relief there. Since the war especially, and in contrast to gout, the disease had increased. Not more than 10 per cent. of the cases recovered; but it was something from a patient's point of view to obtain even a slight functional improvement. The ideal was to get the patient to take intermittent courses of treatment, lasting not longer than six to eight weeks; longer courses were undesirable as promoting debility.

Prof. Osgood (Harvard University) feared that it must be confessed that in most cases removal of infected foci did not lead to recovery; in one series, indeed, there had been more recoveries where the foci had *not* been removed. There might, he suggested, be a missing link between a disordered metabolism and an infection. As a result of the presence of toxins often specific in man (and, indeed, often possessing a strict tissue-specificity), the permeability of the perisynovial capillaries might be modified, and a lowering of the basal metabolism induced—a matter of sensitisation.

Sir Robert Jones emphasised the disease as being a conjoint problem for the physician and surgeon. When the surgeon was called in it was usually too late for him to prevent crippling deformities. The natural course of the disease was towards deformity, which it lay in the power of any general practitioner to prevent. The first physical sign of deformity was a spasm of muscles to obtain the position of ease. As a rule the flexors pulled more and more effectively than the extensors, and so deformity of the muscles resulted. Of two types, one proliferative and the other osteophytic, the former was the more difficult to treat owing to the greater pain. He then referred to special joints; in the wrist, for instance, palmar flexion and ulnar deviation might be countered by an appropriate dorsi-flexion splint; flexion of the knees and adduction of the hips could be prevented by posture, sand-bags, and gentle weight extension. Any movements given were only to be within the limits of pain, and the greatest care was to be taken not to permit rash movements, such as, for instance, forcible extension of a knee where posterior displacement of the tibia was present in addition to flexion. Open operation was often of great avail, even in advanced cases; masses could be removed from the joints or arthrodesis performed with very satisfactory results.

Prof. Cawadias (Athens), after referring to the great variability of the factor of resistance of the body to infection, suggested that disordered metabolism of sulphur might contribute to this aspect of the disease. In support of this hypothesis he advanced the following observations: (1) Cases of rheumatoid arthritis lost too much sulphur in the urine. (2) This imperfectly oxidised sulphur pointed to a general defect in oxidation. (3) The fact that there was no increase in the output of ethereal sulphates showed that the increased sulphur did not originate from mere destruction of cartilage.

Dr. J. M. H. Monro reviewed several series of cases, showing that changes in the blood—anæmia, leucopenia, leucocytosis, and complement-fixation—might be found, in contrast to normal blood, in about 80 per cent. of cases of rheumatoid arthritis. The *Streptococcus viridans* appeared to be the usual source of infection, and had been found in the roots of teeth in which the X ray findings had been negative. While cocci were the usual cause of infection, it was not uncommon to find coincident tuberculosis and even syphilis.

Mr. Timbrell Fisher, speaking from a pathological standpoint, proposed to substitute for the older nomenclature of rheumatoid and osteo-arthritis a division of cases into three groups of chronic arthritis: (1) Chondro-osteal type, in which there was a primary degeneration of the more central cartilage, with eburnation of the underlying bone, while the lateral part of the cartilage became hypertrophied. It was only later that the synovial membranes also became hypertrophied, and there was never any small round cell infiltration. These cases, occurring usually in later life, constituted a degenerative group. (2) Mixed type, in which the cartilaginous and synovial changes occurred concurrently. A pannus spread from the synovial membrane into the cartilage, and small round cells were present. Lipping only occurred later. (3) Synovial type, which appeared more inflammatory, with abundant infiltration of small round cells.

Sir W. Willcox regarded infection as the primary cause in the great majority of cases, but was careful to exclude gout, neuropathic joint lesions, and such a condition as intermittent hydrarthrosis from the group under discussion. In support of the infective hypothesis he brought forward the following considerations: (1) Other known organisms—e.g., gonococcus, pneumococcus, and *B. typhosus*—might produce arthritis very similar to rheumatoid arthritis; (2) rheumatoid arthritis frequently followed parturition; (3) an infective focus was almost always discoverable. Dental sepsis accounted for most cases (72 per cent.); the apical infections were not true abscesses causing pain from pressure, but rather necrotic areas. Tonsillar cases were fewer (10 per cent.) and occurred in younger patients especially. Diagnosis of antral infections was often difficult, even with radiography and transillumination, and in such cases it was best to puncture the antrum. The colon was often the seat of infection in elderly patients. Tuberculosis elsewhere was not, in his opinion, an important ætiological factor; on the other hand, he thought that the presence of septic foci predisposed to the development of phthisis. (4) The eradication of the infective focus had usually been followed by cessation of active inflammation. (5) Rheumatoid arthritis was only a manifestation in the joints of a chronic toxæmia. Treatment should aim at the removal of the infective cause, and might include Plombières colon irrigation as an important factor. Only after this removal were vaccines to be employed, and then only in small doses.

Sir J. Barr expressed his belief that acid fermentation in a dilated stomach was the main cause of the disease, and advocated a diet rich in red meat and poor in carbohydrate.

Lord Dawson said that it was an irresistible conclusion that infection played a part. The difficulty lay in the origin and measure of that infection, and hence a speculative removal of teeth and tonsils might be advised. Sometimes the source of infection might be inaccessible; at other times the infection might well be one which under ordinary conditions would have been non-pathogenic. In such cases treatment must be concerned with the raising of resistance. He looked to the bio-chemist to explain the expression "resistance," with the coöperation of the bedside physician. If the results of dental extraction were disappointing, and if it must be admitted that this was an operation of some violence, especially in the aged, yet there was a compensatory satisfaction in observing the increased care which the rising generation was giving to its teeth, even in hospital practice, as a result, he presumed, of its observations of its seniors.

Sir H. Rolleston replied. He referred to the sensitisation hypothesis of Prof. Osgood and to the observations of Prof. Cawadias on sulphur. He had always imagined that sulphur was given as an internal antiseptic. With regard to Lord Dawson's conclusion, he would put the question finally in another way: "Can you," he asked, "have rheumatoid arthritis without infection?"

Thursday, July 23rd.

Hyperpiesia.

Prof. T. R. Elliott having taken the chair, Lord Dawson opened a discussion on hyperpiesia. With a view to the necessity of confining his remarks to certain aspects of hyperpiesia, he postulated the assumption that this was a disease sui generis, involving certain disabilities, of which cardiac and vascular disease was the gravest. But it was better, he considered, in this inquiry not to examine those cases which showed most evidence of cardiovascular wear and tear, but rather to approach the subject through the avenue of youth, thus excluding those graver secondary complications; for it was in later life that hyperpiesia and arterio-sclerosis hunted in couples, and only by excluding the latter might they hope to determine whether hyperpiesia had its beginnings in structural change or in faulty function. The systolic blood pressure reached between the ages of 20 and 45 years the figure of from 115 to 130 mm. Hg; during this period it did not vary much, and he would from his observations view with uneasiness, at that period of life, a fixed systolic pressure of over 140. With exercise, of course, there was a rise, but in health a subsequent fall to normal took place within a few moments of resumption of rest. The studies of Alvarez had shown that of 1500 youths at the University of California 20 per cent. had pressures of over 140. No doubt there was a passing psychological cause for some of these, but it remained a fact that a certain proportion of the young had a true rise of systolic pressure. The diastolic pressure had been less widely studied, but he suggested that at this time of life it lay normally between 75 and 80 mm. Hg, and that at any age a figure of above 100 should be viewed with uneasiness.

Lord Dawson next referred to two families, each of two generations, in one of which no member had a systolic blood pressure of above 110, while in the other no member had a pressure of below 130. These examples prompted two reflections: (*a*) That vaso-constriction played a very varying part in different individuals; and (*b*) that hyperpiesia began as an exaggeration of a quality—in other words, that it began in the realm of physiology to end in that of pathology.

A special investigation had been made in 650 school-children between the ages of 10 and 17, and 52 of these, or 8 per cent., had shown a systolic pressure of over 130 mm. Hg. The observations had been multiplied to exclude factors of excitement, and it had not been found possible to identify hyperpiesia with any particular type of child. Prospects of a school examination did not raise the pressure; on the other hand, the classes for the Oxford Senior Local Examinations, attracting as they did ambitious children, in whom they might be supposed to engender some anxiety as to their prospects in life, showed a relatively high incidence of hyperpiesia in the children attending them. He believed that in these cases the high blood pressure was an expression of a type of mind which was naturally striving and ambitious. In this group of 8 per cent. one could fairly rule out any degenerative structural process; it was more likely that these cases showed an inborn peculiarity of function, which might become so accentuated as to produce damage in varying degree. Correction might be effected by choice of suitable careers; otherwise vaso-constriction, progressively provoked by slighter and slighter stimuli, might cause a condition of high pressure to become more or less permanent.

A more detailed investigation of nine cases selected from the same group had elicited more definite support of this view; these were all boys, and showed in most cases, in addition to the raised systolic pressure, palpable radial arteries and accentuated aortic second sounds; in four, moreover, there was hypertrophy of the left ventricle, and in three a blood-urea of over 0·050 per cent. One case had a urea concentration of under 1·5 per cent. As would be expected, there was considerable variation among these cases; they merged on the one hand with a physiological, and on the other with a pathological state, those showing the most definite cardiac hypertrophy being those subjected to the greatest strain. Pathological evidence was, of course, not easily forthcoming; but in one exceptional case of a girl, often showing a pressure of 240 mm. Hg systolic and 140 diastolic at the age of 10, it had been possible during an operation for decapsulation of the kidneys to secure portions of the organs for examination. Lord Dawson showed these sections on the epidiascope. They illustrated (1) marked hypertrophy of the tunica media of the larger arteries; (2) slight fatty degeneration of the intima of the smaller arteries; and (3) patches of partial atrophy of the tubules due to small round cell infiltration.

In later life high blood pressure might supervene upon a normal pressure in youth, and here it was necessary to consider, in addition to family or individual predisposition, the possible effects of chemical agencies, of pressor substances (such as guanidine derivatives), and of the products of erroneous metabolism. But in his view hyperpiesia had its chief origin as a habit of body and mind, systemic circulation, might be a contributory cause of the disease; in such cases also the small rather than the large intestine appeared to act as a source of infection. In the genito-urinary tract the *B. coli* might act as an infective agent in a few cases, especially when harboured in the prostate. The respiratory tract, apart from cases of pulmonary arthropathy, could for practical purposes be exonerated. Although the opinion held in France that some cases of rheumatoid arthritis might be due to the toxins of the tubercle bacillus found little or no support in England, yet it was worth bearing in mind a possible analogy between syphilis and parasyphilitic disease on the one hand and tuberculosis and rheumatoid arthritis on the other. He referred also to the occasional association of arthritis with psoriasis and impetigo, and suggested that an anaphylactic relationship might exist between them. The chief objections to the infective theory were that people often have infective foci but no arthritis, and that in many cases we can find no infective focus. The uncertain factor of the soil, however, was to be borne in mind in weighing such objections, and search for a possible focus—e.g., in the prostate or nasal sinuses—was often incomplete. Again, certain foci of infection might be "closed"—the gall-bladder, for example—or one joint might act as a reservoir of infection for other joints. From the bacteriological standpoint it was usually a streptococcus that was incriminated, but there was often difficulty in recovering the organism from the synovial fluid and membranes.

As to treatment, prevention was the keynote. Eradication of infection, as. for instance, in dental extraction, must be complete. Just as a match was as effective as a torch in firing a train of gunpowder, so a small focus of infection might set up an arthritis as severe as a large one. Dead teeth were a favourite seat for infecting organisms, and there was consequently a danger in killing the nerves of teeth. As to encouraging the soil, he referred to the possibility of stimulating metabolism by thyroid extract, parathyroid, arsenic, iodine, and heliotherapy, and he drew attention to the theoretical uses of protein shock in therapy.

Mr. W. R. Ackland considered the division of dental sepsis into pyorrhœa and dental abscesses too hard and fast. Apical abscesses sometimes discharged through the gum, while in pyorrhœa, on the other hand the deeper layers could never be properly drained. Gastric juice did not always destroy the streptococcus and it might even liberate an endotoxin. Moreover, there was no gastric juice in the stomach at night, when toxins might pour down into the stomach and ultimately produce achlorhydria, and if the liver functions were affected the infection would pass to the general circulation. The streptococcus appeared to have an especial affinity for a dead tooth. The results of treatment were, on the whole, disappointing. One might at least hope, however, that patients would not get worse thereafter. X rays of the teeth not being infallible, he was in the habit of condemning all bridges, crowns, and dead teeth.

Dr. Rupert Waterhouse, from a hydrotherapeutic standpoint, said that though the infective hypothesis of rheumatoid arthritis was in full swing in Bath 25 years ago, there yet seemed as a result to be no diminution in the number of patients seeking relief there. Since the war especially, and in contrast to gout, the disease had increased. Not more than 10 per cent. of the cases recovered; but it was something from a patient's point of view to obtain even a slight functional improvement. The ideal was to get the patient to take intermittent courses of treatment, lasting not longer than six to eight weeks; longer courses were undesirable as promoting debility.

Prof. Osgood (Harvard University) feared that it must be confessed that in most cases removal of infected foci did not lead to recovery; in one series, indeed, there had been more recoveries where the foci had *not* been removed. There might, he suggested, be a missing link between a disordered metabolism and an infection. As a result of the presence of toxins often specific in man (and, indeed, often possessing a strict tissue-specificity), the permeability of the perisynovial capillaries might be modified, and a lowering of the basal metabolism induced—a matter of sensitisation.

Sir Robert Jones emphasised the disease as being a conjoint problem for the physician and surgeon. When the surgeon was called in it was usually too late for him to prevent crippling deformities. The natural course of the disease was towards deformity, which it lay in the power of any general practitioner to prevent. The first physical sign of deformity was a spasm of muscles to obtain the position of ease. As a rule the flexors pulled more and more effectively than the extensors, and so deformity of the muscles resulted. Of two types, one proliferative and the other osteophytic, the former was the more difficult to treat owing to the greater pain. He then referred to special joints; in the wrist, for instance, palmar flexion and ulnar deviation might be countered by an appropriate dorsi-flexion splint; flexion of the knees and adduction of the hips could be prevented by posture, sand-bags, and gentle weight extension. Any movements given were only to be within the limits of pain, and the greatest care was to be taken not to permit rash movements, such as, for instance, forcible extension of a knee where posterior displacement of the tibia was present in addition to flexion. Open operation was often of great avail, even in advanced cases; masses could be removed from the joints or arthrodesis performed with very satisfactory results.

Prof. Cawadias (Athens), after referring to the great variability of the factor of resistance of the body to infection, suggested that disordered metabolism of sulphur might contribute to this aspect of the disease. In support of this hypothesis he advanced the following observations: (1) Cases of rheumatoid arthritis lost too much sulphur in the urine. (2) This imperfectly oxidised sulphur pointed to a general defect in oxidation. (3) The fact that there was no increase in the output of ethereal sulphates showed that the increased sulphur did not originate from mere destruction of cartilage.

Dr. J. M. H. Monro reviewed several series of cases, showing that changes in the blood—anæmia, leucopenia, leucocytosis, and complement-fixation—might be found, in contrast to normal blood, in about 80 per cent. of cases of rheumatoid arthritis. The *Streptococcus viridans* appeared to be the usual source of infection, and had been found in the roots of teeth in which the X ray findings had been negative. While cocci were the usual cause of infection, it was not uncommon to find coincident tuberculosis and even syphilis.

Mr. Timbrell Fisher, speaking from a pathological standpoint, proposed to substitute for the older nomenclature of rheumatoid and osteo-arthritis a division of cases into three groups of chronic arthritis: (1) Chondro-osteal type, in which there was a primary degeneration of the more central cartilage, with eburnation of the underlying bone, while the lateral part of the cartilage became hypertrophied. It was only later that the synovial membranes also became hypertrophied, and there was never any small round cell infiltration. These cases, occurring usually in later life, constituted a degenerative group. (2) Mixed type, in which the cartilaginous and synovial changes occurred concurrently. A pannus spread from the synovial membrane into the cartilage, and small round cells were present. Lipping only occurred later. (3) Synovial type, which appeared more inflammatory, with abundant infiltration of small round cells.

Sir W. Willcox regarded infection as the primary cause in the great majority of cases, but was careful to exclude gout, neuropathic joint lesions, and such a condition as intermittent hydrarthrosis from the group under discussion. In support of the infective hypothesis he brought forward the following considerations: (1) Other known organisms—e.g., gonococcus, pneumococcus, and *B. typhosus*—might produce arthritis very similar to rheumatoid arthritis; (2) rheumatoid arthritis frequently followed parturition; (3) an infective focus was almost always discoverable. Dental sepsis accounted for most cases (72 per cent.); the apical infections were not true abscesses causing pain from pressure, but rather necrotic areas. Tonsillar cases were fewer (10 per cent.) and occurred in younger patients especially. Diagnosis of antral infections was often difficult, even with radiography and transillumination, and in such cases it was best to puncture the antrum. The colon was often the seat of infection in elderly patients. Tuberculosis elsewhere was not, in his opinion, an important ætiological factor; on the other hand, he thought that the presence of septic foci predisposed to the development of phthisis. (4) The eradication of the infective focus had usually been followed by cessation of active inflammation. (5) Rheumatoid arthritis was only a manifestation in the joints of a chronic toxæmia. Treatment should aim at the removal of the infective cause, and might include Plombières colon irrigation as an important factor. Only after this removal were vaccines to be employed, and then only in small doses.

Sir J. Barr expressed his belief that acid fermentation in a dilated stomach was the main cause of the disease, and advocated a diet rich in red meat and poor in carbohydrate.

Lord Dawson said that it was an irresistible conclusion that infection played *a* part. The difficulty lay in the origin and measure of that infection, and hence a speculative removal of teeth and tonsils might be advised. Sometimes the source of infection might be inaccessible; at other times the infection might well be one which under ordinary conditions would have been non-pathogenic. In such cases treatment must be concerned with the raising of resistance. He looked to the bio-chemist to explain the expression "resistance," with the coöperation of the bedside physician. If the results of dental extraction were disappointing, and if it must be admitted that this was an operation of some violence, especially in the aged, yet there was a compensatory satisfaction in observing the increased care which the rising generation was giving to its teeth, even in hospital practice, as a result, he presumed, of its observations of its seniors.

Sir H. Rolleston replied. He referred to the sensitisation hypothesis of Prof. Osgood and to the observations of Prof. Cawadias on sulphur. He had always imagined that sulphur was given as an internal antiseptic. With regard to Lord Dawson's conclusion, he would put the question finally in another way: "Can you," he asked, "have rheumatoid arthritis without infection?"

THURSDAY, JULY 23RD.

Hyperpiesia.

Prof. T. R. Elliott having taken the chair, Lord Dawson opened a discussion on hyperpiesia. With a view to the necessity of confining his remarks to certain aspects of hyperpiesia, he postulated the assumption that this was a disease sui generis, involving certain disabilities, of which cardiac and vascular disease was the gravest. But it was better, he considered, in this inquiry not to examine those cases which showed most evidence of cardiovascular wear and tear, but rather to approach the subject through the avenue of youth, thus excluding those graver secondary complications; for it was in later life that hyperpiesia and arterio-sclerosis hunted in couples, and only by excluding the latter might they hope to determine whether hyperpiesia had its beginnings in structural change or in faulty function. The systolic blood pressure reached between the ages of 20 and 45 years the figure of from 115 to 130 mm. Hg; during this period it did not vary much, and he would from his observations view with uneasiness, at that period of life, a fixed systolic pressure of over 140. With exercise, of course, there was a rise, but in health a subsequent fall to normal took place within a few moments of resumption of rest. The studies of Alvarez had shown that of 1500 youths at the University of California 20 per cent. had pressures of over 140. No doubt there was a passing psychological cause for some of these, but it remained a fact that a certain proportion of the young had a true rise of systolic pressure. The diastolic pressure had been less widely studied, but he suggested that at this time of life it lay normally between 75 and 80 mm. Hg, and that at any age a figure of above 100 should be viewed with uneasiness.

Lord Dawson next referred to two families, each of two generations, in one of which no member had a systolic blood pressure of above 110, while in the other no member had a pressure of below 130. These examples prompted two reflections: (*a*) That vaso-constriction played a very varying part in different individuals; and (*b*) that hyperpiesia began as an exaggeration of a quality—in other words, that it began in the realm of physiology to end in that of pathology.

A special investigation had been made in 650 school-children between the ages of 10 and 17, and 52 of these, or 8 per cent., had shown a systolic pressure of over 130 mm. Hg. The observations had been multiplied to exclude factors of excitement, and it had not been found possible to identify hyperpiesia with any particular type of child. Prospects of a school examination did not raise the pressure; on the other hand, the classes for the Oxford Senior Local Examinations, attracting as they did ambitious children, in whom they might be supposed to engender some anxiety as to their prospects in life, showed a relatively high incidence of hyperpiesia in the children attending them. He believed that in these cases the high blood pressure was an expression of a type of mind which was naturally striving and ambitious. In this group of 8 per cent. one could fairly rule out any degenerative structural process; it was more likely that these cases showed an inborn peculiarity of function, which might become so accentuated as to produce damage in varying degree. Correction might be effected by choice of suitable careers; otherwise vaso-constriction, progressively provoked by slighter and slighter stimuli, might cause a condition of high pressure to become more or less permanent.

A more detailed investigation of nine cases selected from the same group had elicited more definite support of this view; these were all boys, and showed in most cases, in addition to the raised systolic pressure, palpable radial arteries and accentuated aortic second sounds; in four, moreover, there was hypertrophy of the left ventricle, and in three a blood-urea of over 0·050 per cent. One case had a urea concentration of under 1·5 per cent. As would be expected, there was considerable variation among these cases; they merged on the one hand with a physiological, and on the other with a pathological state, those showing the most definite cardiac hypertrophy being those subjected to the greatest strain. Pathological evidence was, of course, not easily forthcoming; but in one exceptional case of a girl, often showing a pressure of 240 mm. Hg systolic and 140 diastolic at the age of 10, it had been possible during an operation for decapsulation of the kidneys to secure portions of the organs for examination. Lord Dawson showed these sections on the epidiascope. They illustrated (1) marked hypertrophy of the tunica media of the larger arteries; (2) slight fatty degeneration of the intima of the smaller arteries; and (3) patches of partial atrophy of the tubules due to small round cell infiltration.

In later life high blood pressure might supervene upon a normal pressure in youth, and here it was necessary to consider, in addition to family or individual predisposition, the possible effects of chemical agencies, of pressor substances (such as guanidine derivatives), and of the products of erroneous metabolism. But in his view hyperpiesia had its chief origin as a habit of body and mind and crept into life without subjective symptoms; so that unless it were disclosed by a fortunate medical examination it might latently lead to actual structural disease.

Prof. E. H. Starling emphasised the extreme importance of the blood-supply to the vaso-motor centre in the medulla. This centre did not control its own blood-supply by vaso-motor fibres, but did so indirectly by controlling the pressure elsewhere. A raising of the blood pressure in the circle of Willis was compensated for by a lowering of the pressure elsewhere, and vice versa. This condition was demonstrated by an illustration of an experiment, in which it was shown that if the intracranial contents of a dog were cut off from the heart and connected with the heart of another dog, any variation which might be produced in the blood pressure in the cranial arteries was compensated for by an opposite change in the blood pressure in the other parts of the body, this change taking place at similar rate to that of the variation of the cranial blood pressure. The chief factors involved in maintaining blood pressure were: (1) The output of the heart, which was proportional to the flow into the heart; and (2) the peripheral resistance, which was under the control of the vaso-motor centre, and was chiefly regulated in the splanchnic area. Thus in man the pressure was maintained at 85 to 130 mm. Hg. But, he asked, what determined the average height? The answer was that the blood pressure was determined by the blood-supply that was necessary for the brain; thus even in heart failure the pressure must not fall, since at all costs the blood-supply to the medulla must be maintained.

In hyperpiesia the pressure was set at a higher level, and any oscillation took place around it. He submitted that the change in the level had to be effected and maintained because otherwise the vaso-motor centre would not receive an adequate amount of blood for its needs. Pursuing this line of thought, they might inquire what were the conditions under which the vaso-motor centre would, without a rise of blood pressure, obtain an insufficient blood-supply. These might be (1) gross changes in the vessels; (2) claudication; and (3) arterial spasm; but, more important than these, seemed to be (4) changes in the capillary walls—i.e., alterations in size and in permeability. If from such causes the pressure in the peri-capillary lymphatics were raised (a condition possibly present in uræmia and the toxæmias of pregnancy, and in the condition he referred to as "wet-brain," accompanied by transient paralyses) this peripheral pressure would explain the rise of general blood pressure necessary to overcome it. There was no evidence that a diseased kidney was directly responsible for the raised blood pressure. Cohnheim, indeed, regarded a rise of pressure in renal disease as compensatory; but even so the stimulus could only act through the vaso-motor centre. In conclusion, he submitted that in investigating any possible prime cause of hyperpiesia, it should always first be asked how that cause could modify the blood-supply to the vaso-motor centre in the medulla.

Dr. McCrae (Philadelphia) expressed his feeling that the most obvious things about blood-tension were the difficulties it presented. In certain cases of childhood a raised pressure appeared a temporary condition, in others it persisted; possible causes were organic disease and infections, early renal changes, and, in the case of hypo-pituitarism and the menopause endocrine influences. He wished particularly to emphasise the fact that here for the general practitioner was an opportunity for clinical research over a length of time such as hospital and consulting practice did not offer.

Dr. Batty Shaw said that he believed the main origin of hyperpiesia was toxic. The vaso-motor centre was not the only site of nervous control of the vessels; there was also the neuro-muscular plate, and he submitted that this point of junction might be affected by chemical agents. What were the toxic agents? Not, he thought, infective poisons which were depressor in their action, but such pressor substances as were derived from the suprarenal, the pituitary, and the renal cortex. He stressed the importance of recording the daily blood pressure as regularly as the pulse and temperature, and reported a case of hyperpietic crisis in which the pressure had suddenly dropped from 230 to 130 with accompanying coma and high blood-urea, and almost as quickly returned to the original level. He ascribed such changes to physiologically antagonistic toxins.

Dr. Otto May, speaking as medical officer to the Prudential Assurance Co., Ltd., while admitting that many sources of error arose in estimating the blood pressure of an individual, held that, where statistical calculations depended upon a very large number of cases, the individual fallacies became of relatively little importance. Such statistics showed that an increased systolic pressure was a definite menace to longevity; with pressures over 170 the outlook got rapidly worse, while at 200 and over the mortality was eight times the normal. He referred with regret to the relatively slight use made by medical men of the sphygmomanometer as compared with the stethoscope. He made his opinion quite clear that statistical information, even of the clearest kind, was not to be applied in individual cases without due consideration of other factors in the physical condition.

Dr. Geoffrey Evans, after reference to early researches which had not confirmed anatomical changes expected in cases dead with hyperpiesia, remarked that in the natural experiment of chronic interstitial nephritis they were now able to observe that hypertension and vascular disease were not necessary accompaniments of renal disease. He believed in the toxic origin of hyperpiesia, but was more concerned with the condition itself. Hyperpiesia was a clinical state quite independent of the kidneys; as Sir Clifford Allbutt had said, it did not end in nephritis—its evolution was rather towards heart disease and hæmorrhage. Its hall-mark was cardiac hypertrophy, as demonstrated by X rays and the electro-cardiograph. Retinal vascular changes and modifications of the aortic second sound were other characteristics of it. The morbid anatomy was quite definite, as compared, for instance, with that of a case of migraine. In hyperpiesia the body was plethoric, the heart large, and there was a definite hypertrophy of the arterial walls best seen on macroscopic section of the otherwise normal spleen and kidneys. Microscopically, the intima appeared swollen with endothelial cell-proliferation, which, being avascular, went on to fatty degeneration of the intima. The tunica media might or might not be hypertrophied, or the hypertrophy might be apparent only.

Dr. F. H. Humphris referred to benefits in hyperpiesia from electrical treatment; he maintained that every application produced a lowering of the maximal arterial pressure by 10 per cent.

Dr. W. Salisbury-Sharpe, from a study of 500 men of between the ages of 60 and 65, had found that a considerable degree of activity was compatible with high blood pressure.

Dr. A. Cawadias regarded hyperpiesia as a syndrome. Two diagnoses were necessary: (1) Diagnosis of the syndrome itself; here it must be recognised that there were local hyperpieses giving rise to crises—e.g., in the lower limbs and the heart. (2) Diagnosis of the cause. The influences which might act upon the vaso-motor centre were: (a) toxic—as in nephritis; (b) chemical—e.g., adrenalin; and (c) nervous. He considered the investigation of youth to be the best avenue of research.

Dr. Stacey Wilson referred to varying differences between estimations of the blood pressure made by different methods—e.g., tactile and auscultatory. He regarded these peculiarities as worthy of investigation by general practitioners. In one case the auscultatory method gave the higher reading, in another the tactile. Why was this? He was sure that toxic conditions were important: syphilis alone *was evidence enough of this.*

Prof. R. J. S. McDowall believed that in emotional and toxic states there was a condition of strain, as a result of which a functional overaction took place. He would cut down the protein of the diet in hyperpiesia.

Lord Dawson, in replying, said it was difficult to believe that hyperpiesia in children was toxic; an innate tendency in them seemed much more probable. Anxiety, and especially repressed anxiety, might raise the pressure and possibly there was a metabolic factor. But the border-line between functional error and morbid entity seemed to him, in this case at any rate, to be a blurred one.

Friday, July 24th.

The Uses and Abuses of Endocrine Therapy.

In opening the discussion on this subject, Lord Dawson being in the chair, Dr. W. Langdon Brown said that he would deal with the uses of endocrine therapy, leaving Prof. Swale Vincent to deal with the abuses. An endocrine preparation might be used either to replace a deficient internal secretion (thyroid, insulin) or for its pharmacological action (adrenalin). But before it could be used on a rational basis it must be shown that the gland in question forms an internal *secretion; that its active* principles can be extracted; and that the extract can be so administered as to admit of its utilisation by the body. In very few instances had all these criteria been satisfied, so that clinicians had been forced into more empirical methods. Empiricism had won success in other spheres—e.g., quinine, salicylates, and, previous to the discovery of vitamins, cod-liver oil—and moreover the functions of the thyroid itself had been made out at the bedside. Nevertheless, the empirical method was to be used critically, and the study of the basal metabolic-rate and of the blood-sugar curve had recently been useful in confirming the effects of extracts: of more limited use at present was the estimation of the calcium of the *blood.*

Thyroid extract fulfilled all the above criteria; its principle was a general quickener of metabolism. A total daily dose of 6 gr. of the extract of the fresh gland (which was one-fifth as strong as that of the desiccated gland) needed seldom to be exceeded. It was worth using in children suffering from stunted growth, nocturnal enuresis, night-terrors, and relaxation of ligaments—e.g., knock-knee, flat-foot, and lordosis—as well as in cases presenting the stigmata of hypothyroidism; it was the great stimulant to growth. Where growth was complete, thyroid was an agent katabolic of those products of incomplete combustion which, in conditions of thyroid deficiency, infiltrated many of the tissues.

The use of *parathyroid* extract was more justifiable now that Collip had isolated its active principle. Its uses were: (1) Sedative to the nervous tissues (e.g., in tetany, petit-mal, and eclampsia) by effecting a rise in the blood calcium, and (2) to promote healing in chronic sepsis (chronic gastric ulcer, varicose ulcer). It was absorbed when given by the mouth. There was a mass of evidence pointing to *adrenalin* as a general sympathetic stimulant to be used in such emergencies as *acute asthma*, vaso-motor paralysis, heart failure, and hypoglycæmia, but it was of little or no use for substitution therapy in Addison's disease. Extracts of the anterior lobe of the *pituitary* certainly appeared to have given results, when administered orally, in cases of deficient growth from pituitary insufficiency. As to the posterior lobe, he believed that its secretion, pituitrin, had an important association with the reproductive processes, in support of which belief he mentioned among others the following *observations*: (1) Fröhlich's syndrome was always associated with undeveloped sexual organs. (2) Dixon and Marshall had shown that a corpus luteum in the ovary in pregnancy could completely inhibit the action of ovarian extract which normally, on injection, caused an immediate flow of pituitrin into the cerebro-*spinal fluid. Just before parturition*, however, the ovarian extract would again, on injection, profoundly stimulate the production of pituitrin, leading to uterine contractions and lactation. Similarly, he had found clinically that an extract of corpus luteum soon stopped excessive lactation in a woman who had an enlarged pituitary fossa. Diabetes insipidus, believed to be associated with posterior lobe deficiency, had been treated with some success by spraying *extracts of pituitary into the nose.*

Speaking of *pancreatic* extracts, there could be no doubt of the efficacy of insulin and there were considerable numbers of patients who, having had a course of insulin, had later been able to give it up and yet to keep free of glycosuria. Dr. Langdon Brown protested strongly against statements which led patients to deprive themselves of this most valuable remedy of diabetes. Insulin had also been used tentatively for hyperthyroidism, and it should be used *in the acute* hyperthyroidism following operations on the thyroid gland. It could reduce the basal metabolic rate. It might be hoped that *ovarian* extracts, recently shown by Allen and Doisy to produce definite effects, might, *if they could be freed* from corpus luteum, benefit ovarian inadequacy, especially in the miseries of the climacteric in woman. He was sceptical as to the value of other endocrine extracts, though in the case of the testis the grafting method offered a chance of effective treatment.

Prof. Swale Vincent said that there should be no essential difference between the nature of observations made by laboratory workers and clinical workers. It was the duty of the latter, as of the former, to carry out an experiment if an opportunity presented itself. The difficulty for him appeared to lie in making satisfactory, or indeed any, criteria to justify the term "*experiment.*" *It was, for instance*, useless to claim that a drug had done good, unless they had a moderately clear idea of what would have happened if the drug had not been used; yet this obvious consideration had been universally overlooked even by medical men, and the public had not even begun to be suspicious of the resulting and blatant advertisement of the drug vendor. Again, he contended that the information derived from the observation of the effects of juices squeezed out of certain organs did not *justify at all* the assumption that the physiological action of those organs was the same as the pharmacological action of their extracts. If this were so the extirpation of the organs should produce effects exactly opposite to the *effects of injecting the extracts.* This did not occur. For instance, extirpation of the adrenal glands did not cause an immediate fall in blood pressure. Similarly, to prove that pituitrin was the internal secretion of the pituitary, it was not enough to obtain it by extraction from the gland.

If this erroneous type of conclusion were accepted —that the pharmacological effect of an extract justified the assumption of a similar physiological effect of the gland from which it was obtained—*what were they to* say about the other ductless glands and tissues? All tissue extracts in general (other than those of the adrenals and pituitary) had the effect of lowering the blood pressure, and by this argument it was rational to supply every month a *new* substitution product or hormone for lowering the blood pressure, derived from each tissue whose extract had been examined. In France it had been argued that each tissue produced its own substance for lowering its own local *blood* pressure. It could not be urged too strongly that the effects of these extracts were not specific and had nothing to do with any internal secretion on the part of the tissue in question. To argue that because extracts of the cerebral cortex lowered the blood pressure, it was therefore one of the functions of the cerebral cortex to manufacture and pour into the circulation a hormone, the duty of which was to keep down the blood pressure, would be absurd. Many physicians, however, had not claimed that their endocrine practice was based on sound physiological data, but had insisted on the empirical value of endocrine extracts. While there was no objection to this attitude, it was only reasonable that the a posteriori evidence of relief or cure must be satisfactory. In many instances this was far from being the case, and the scientific value of conclusions drawn under such circumstances was nil.

His conclusions were that there were only two clear cases where they could employ a true substitution therapy—those of the thyroid and the pancreas; and only the thyroid was known to produce effects when given by the mouth. The cases, however, of the parathyroid and the ovary were perhaps in a transitional stage, and the preparation made by Allen and Doisy from the ovaries appeared to be active if injected hypodermically. Out of the long list of preparations of 42 organs and tissues advertised by the manufacturing druggists and prescribed by the "clinical endocrinologists," only one—the thyroid—was of proven value when given by the mouth.

Dr. Gardiner Hill spoke about work done by the St. Thomas's Hospital Medical Unit upon thyroid and pituitary therapy. (1) In obesity thyroid extract had been given by the mouth together with whole gland pituitary. Many of the cases were women at the menopause or just after parturition. Their sugar-tolerance curves differentiated two groups—namely, recent cases, in which there was a slowly decreasing sugar tolerance, and longer established cases, in which the sugar tolerance was high. In the latter group thyroid was useful. The more recent cases of the first group were some of them potential diabetics. Whole gland pituitary helped the sugar curve to fall. (2) In undergrown children feeding with extract of anterior lobe of pituitary was useful, and the rate of growth might be more than doubled by this means, which also increased the sugar tolerance in every case. Giving thyroid in addition produced an even greater effect, which could be to some extent checked by estimation of the basal metabolism. Orchitic and ovarian extracts had been found quite ineffective in cases of amenorrhœa.

Mr. Kenneth Walker spoke from the surgical aspect only, and formulated certain principles concerning living transplants. (1) The more nearly related the donor to the host, the more successful the effects; grafts from another species from that of the host were rapidly absorbed owing to the development of fibrous tissue in the graft and leucocytic invasion from the host. (2) Different tissues disappeared with different rapidity—e.g., the medulla of the adrenal quickly disappeared while the cortex might survive. (3) In transplantation experiments it was possible to feminise male guinea-pigs only if they had been castrated, and to masculinise female guinea-pigs only after removing the ovaries. (4) A successful graft had to be calculated to supply a deficiency; any excess of material transplanted was apparently physiologically inert. There was still much to be understood in the varying relations between the host cells and the transplant.

Dr. H. W. C. Vines described endocrine therapy as an undeveloped science. They were attempting to discuss it as though it was fully understood, and he strongly deprecated destructive criticism, whilst admitting the danger of enthusiasm. In such a science there was necessarily empiricism, but so also was there in vitamin and light therapy, and in treatment even by simple drugs like squill. He had recently obtained some evidence that the influence of parathyroids upon the blood-calcium was due to a protective colloid, which kept certain organic complexes of calcium and lecithin from precipitation. From experiments he had made in vitro it appeared probable that a quantitative relationship might be found between the amount of parathyroid substance used and the calcium content of experimental solutions. It was not surprising, therefore, that in tetany the oral administration of parathyroid was generally such a failure, while grafts or extracts injected might cure the condition; for it was a question of the maintenance in the blood of a definite quantity of that protective substance. With regard to sprue, he pointed out four things: (1) Dr. Scott had had no success from the use of calcium salts. (2) He had had good results from using the "commercial" extracts of parathyroid with calcium salts. (3) The giving of thyroid invariably caused a relapse. (4) Scott's work had been confirmed by the work of other observers.

Prof. F. Langmead said that while Dr. Langdon Brown had emphasised the value of trial in endocrine therapy, many of the trials were not real tests at all, comprising too often the use of substances they had no knowledge of, in strengths which were quite uncertain, for treating diseases which were not understood. The value of thyroid medication in cretins was, of course, indubitable. He had also seen good results in rheumatoid arthritis and in large goitres of puberty, but he thought it was of no value in enuresis. Referring to certain observations of Mr. Kenneth Walker, he stated that large quantities of the gland might be taken without any signs of overdose. He asked, referring to parathyroid, where it all came from? He thought much of the work on the blood-calcium to be worth little, owing to sources of error in the estimations. He did not believe that adrenalin when swallowed could reach the stomach in sufficient strength to be of use in gastrostaxis. He agreed that pituitary when given by the mouth had a pharmacological action by influencing the blood-sugar. Cases of "hypopituitarism" were a mixed lot, compared with true Fröhlich cases which were rare. The blood-sugar was the criterion of true hypopituitarism. Dr. Langdon Brown had only attempted to claim results for six glands, so that the long list of suggestions for organotherapy fully justified the cold douche of Prof. Swale Vincent.

Dr. Woods Hutchinson (U.S.A.) considered that only six or seven out of 72 American endocrine preparations were active. He referred to the great importance of sodium iodide in diminishing the frequency of goitre in the States.

Sir James Berry professed himself whole-heartedly in agreement with Prof. Swale Vincent. He particularly protested against statements made with regard to the use of parathyroid in tetany, which was not probably due to parathyroid deficiency at all; the laboratory work on this subject had impressed him unfavourably. He considered that the term hyperthyroidism was used too loosely; it was sometimes applied to people with enlarged thyroid glands who happened to have a rapid pulse. If anything, these people were *hypo*-thyroidic. He suggested the term dysthyroidism as useful; symptoms might be very mixed—e.g., myxœdema with tachycardia. Iodine was good for early goitre of childhood, but too much of it might produce a true hyperthyroidism. Lack of iodine, however, was not the cause of endemic goitre any more than lack of quinine was the cause of malaria.

Dr. J. A. Nixon asked who it was that was creating the demand for the 72 inactive endocrine products, and would confess to doing so. The meeting would fortify the recipients of daily advertisements to resist them.

Dr. Langdon Brown, in replying, referred to a direct relationship existing between the basal metabolic rate and the pulse-pressure (excluding, of course, cases of aortic regurgitation). A pulse pressure of over 40 meant a basal metabolic rate above normal; this might be very useful in deciding whether cases of enlarged thyroid at puberty were hyper- or hypothyroidic. In many cases of tetany the calcium content of the blood was lowered, and the use of parathyroid, which raised the blood calcium, was justified.

Prof. Swale Vincent, replying, said that a certain measure of agreement between the two sides was beginning to appear. It was the advertising pamphlets and those medical men who wrote papers for them that required attacking.

JOINT MEETING OF THE SECTIONS OF DISEASES OF CHILDREN AND OF PUBLIC MEDICINE.

WEDNESDAY, JULY 22ND.

RHEUMATIC INFECTION IN CHILDHOOD.

THIS joint meeting was held under the Presidency of Dr. Robert Hutchison. Dr. F. J. Poynton (London), in introducing the subject, said there was no issue in practical medicine more important and more full of possibilities. Rheumatic heart disease was a frequent event under 12 years of age and a great cause of suffering and early death. In the young the heart had great recuperative powers if it was only rested and protected. There were many people with organic rheumatic heart disease living quiet useful lives and often doing more for the community than many a headstrong hale citizen who squandered his life in riotous living. Since chorea was so frequent among school-children in our large towns, there must surely be, he said, some discoverable factor straining the nervous system. He was not sanguine as to the eradication of this disease in the near future, but a great advance could be made by more careful organisation, greater supervision, and more widespread study. The first essential was to come to a decision as to what symptoms were good evidence of acute rheumatism. When the machinery was in better working order the inquiry could be extended to border-line cases. When county hospitals with facilities for prolonged rest, supervision, and education were established, it would be better to use them at first chiefly for children recovering from a first attack of rheumatic heart disease or from slight damage rather than for chronic cases. They would then be able to convince the public of the good achieved, and money would be forthcoming for the extension of the work. In the Hartfield Hospital in Sussex, established by the Children's Invalid Aid Association, for girls up to 15 and small boys, encouraging results had been obtained. Out of 123 rheumatic children admitted only two, after a period of much cold and rain in the first week in March, developed fever and rheumatic pains, whereas in London, during the same period from October, 1924, onwards, many cases of acute rheumatism, he said, were admitted to his hospital wards. The Hartfield Hospital was run on open-air lines, and although when it began its work the climatic conditions could not have been worse, the children gained remarkably in health and strength and their cardiac condition improved. Until we have a specific remedy for rheumatism, he said, the best we can do is to build up the body tissues. After puberty the tendency to cardiac rheumatism diminishes.

Further study would teach us what home surroundings were specially detrimental. We needed to know more about the modes of onset. The speaker's records of 1108 probable first attacks of acute rheumatism under 12 years of age showed 973 cases of carditis, 620 of arthritis, 617 of chorea, 344 of sore-throat, and 94 of nodules. One group of cases began with sore-throat, arthritis, and morbus cordis. A second group began with chorea, frequently accompanied by morbus cordis. A third, fortunately a small group, began with symptoms of great severity: fever, vomiting, diarrhœa, or sore-throat, followed by arthritis, carditis, nodules, rapid anæmia, and even chorea. Such fulminating attacks were most frequent in the younger children and in those with a strong family tendency to rheumatism. Such a first attack might prove fatal or leave the child terribly injured. A fourth group began with less acute though definite symptoms. These symptoms subsided, but left the child with fleeting pains, shortness of breath, and a tendency to develop the "rheumatic state." In such cases the first early dilatation of the heart was the key to the situation and was easily overlooked. In another group of cases one manifestation alone, such as chorea, was predominant. There were exceptions, but it was advisable to consider all cases of chorea as of rheumatic origin. From the aspect of prevention Dr. Poynton attached great importance to chorea, which was so frequently associated with the most important of all cardiac lesions—namely, mitral stenosis. It also suggested nerve over-strain as a factor predisposing to acute rheumatism. He was convinced that a widespread inquiry into the subject of chorea by school medical officers would supply valuable information. Heart disease as a sole manifestation was even more important than chorea. The most frequent early heart lesion was dilatation, and the percussion of the deep cardiac dullness in childhood was a remarkably accurate method of investigation. Another group of cases began with sore-throat, enlarged cervical glands, fleeting pains, and dilatation of the heart, and this group was easily overlooked. Much had been written against laying undue stress upon cardiac murmurs, but a cardiac murmur in a child always needed consideration. With Dr. Paine the speaker had been responsible for establishing the doctrine of the local focus in rheumatic disease, and the modern doctrine of enucleation of the tonsils was founded on this theory. He believed that the time had come when we were justified in pressing upon the public the need for a concerted effort to protect our children from the effects of rheumatism.

Dr. Robert A. Askins (deputy M.O.H., Bristol) stated that the school medical department of Bristol had been for some years paying attention to this problem, and paid a tribute to the enthusiasm of Dr. Carey Coombs, of the Bristol General Hospital, and Dr. C. E. K. Herapath, of the Bristol Royal Infirmary, in investigating the clinical condition of a large number of their cases. Dr. Coombs had found that about two-thirds of the cases of rheumatic heart disease in Bristol began between the ages of 5 and 15. He estimated that probably between 12,000 and 20,000 deaths occurred annually in England and Wales from rheumatic heart disease contracted during the school age. Our knowledge of the cause of acute rheumatism was so limited that we were unable at present to suggest measures for its prevention. In his opinion the disease was due to an organism of low infectivity with a special condition, such as prolonged or massive dosage. There were in addition secondary factors. He thought that infection rather than heredity was the cause of the disease running in families. If they could not prevent, they could, however, aim at early ascertainment and diagnosis, early treatment and after-care, and training of the cases which were crippled. For early ascertainment the School Medical Service had the opportunities afforded by three medical examinations during school life, and the arrangement by which a child with symptoms could be medically examined at any time, at the instance of teachers and parents. In order to encourage the latter method a circular had been issued in Bristol couched in simple language on lines suggested by Dr. Poynton. For early treatment Dr. Askins favoured the cardiac clinic. Cases should be sent from the cardiac clinic to an open-air country hospital school. When the patient returned from the hospital, training for a suitable occupation should be provided in a branch of a school for cripples. Throughout each stage the child should be under the supervision of medical experts who had special skill in cardiology. He believed a satisfactory scheme could be provided at comparatively small cost. A few cardiac beds under the care of a specialist might be established at each country cripples' hospital. All this work should be carried out by joint action between the clinician and the department of the medical officer of health and be linked up with the work of the voluntary hospitals and of the private practitioner. There was great need for research and the State must help.

Dr. Carey Coombs welcomed alliance between the clinician and the administrator. In order to secure early diagnosis many doubtful cases would have to come under review. Biochemical reactions were of no assistance as yet. They had only physical signs to rely upon. Hospitals must in future supply both open-air and occupation like the Forbes-Fraser Hospital in Bath.

Dr. Reginald Miller referred to the B.M.A. Committee appointed as the result of the discussion at the Portsmouth meeting. Its report was expected shortly and should prove a valuable document for determining the lines of investigation. He also referred to two groups of early rheumatic children, one being composed of highly nervous children, and the other group, with symptoms such as anæmia, night cough and tonsillitis, were frequently mistaken for early tubercle. The Public Health Service must settle the connexion between poverty and rheumatism. Choreic symptoms were not always rheumatic.

Dr. J. A. Glover (Ministry of Health) spoke as to the effect of damp and overcrowded buildings. He also referred to the American idea of moving rheumatic patients to a less rheumatic place. He would like to see the experiment of compulsory notification for five years in two areas with a varying incidence of the disease with a thorough investigation and a mobile research unit attached to each. Lancashire with Manchester as a research centre would be one suitable area.

Dr. Vincent Coates drew attention to a type of small subcutaneous fibroid nodule occurring chiefly along the ulnar border and over the spinous processes, which he had found to be a valuable early sign of rheumatism among the school-children in Bath. (At the close of discussion Dr. Coates demonstrated the presence of these small nodules on a patient (v. p. 326).)

Dr. R. E. Thomas said that it took him three months to learn to palpate the small nodules described by Dr. Coates, but he now relied upon them as a very valuable sign. He did not think these rheumatic affections were associated with poverty but rather with harassed parents. He thought they were more frequent in low-lying districts. They were a common cause of long absence from school, and accounted for 20 per cent. of such absence in London in 1922. (v. p. 326.)

Dr. A. P. Thomson (Birmingham) drew attention to the value of failure in writing as an early sign. The ordinary larger nodules were very rare in Birmingham, and he would be interested to see if Dr. Coates's smaller nodules were equally rare. He thought that the type of rheumatism and the predominant signs varied in different districts. The low-lying sites in Birmingham, near the so-called rivers, seemed to favour the prevalence of rheumatism. He thought house dampness was important and familial prevalence unimportant. It did not appear to be associated with neglected children. There was a hospital for 50 rheumatic children in Birmingham in which the duration of in-patient treatment was long, over six months. Their results from removal of tonsils were encouraging. Out of 70 cases treated only one had persistent valvular disease. Removal of the tonsils seemed to protect against cardiac trouble, but not against rheumatism. He thought the cardiac cases, and especially cases of chorea, should be kept out of general hospitals for cripples. There was no need for special cardiac clinics. Of 60 cases discharged from the Birmingham Hospital 35 had led normal lives for over a year.

Dr. T. Eustace Hill (M.O.H., co. Durham) thought cardiac clinics might be necessary in county areas. He welcomed coöperation with the clinicians.

Dr. Noy Scott (Devon) thought compulsory school attendance in all weathers and damp clothes had a bad effect in rural areas. He also drew attention to the ineffectiveness of modern damp-proof courses, even those sanctioned by the Ministry, and to the harm done by building on unsuitable sites.

Dr. F. E. Wynne (M.O.H., Sheffield) described the constitution of the Sheffield Medical Advisory Committee, which had instituted inquiries with regard to encephalitis lethargica and mammary cancer and intended to take the question of rheumatism in childhood as its third subject for inquiry. He believed that the large amount of routine work in the School Medical Service stood in the way of special inquiries such as they were discussing.

The Chairman emphasised the gravity of the problem and the need for early diagnosis. He hoped for good results from Dr. Coates's new sign. He distrusted the specialists and believed that the medical man with all-round experience was superior to the cardiologist. The financial side was important, as this was now a poor country. Their ignorance of ætiology was the crux of the question. He believed that chorea was associated with the mental strain at school. In his experience rheumatism was not a slum disease, but rather associated with hard-working, successful artisan families.

Reply.

Dr. Poynton, in his reply, hoped for a chief centre of research in London. He agreed that these diseases were not associated with the lowest poverty, but with the artisan class and anxious parents. His reason for objecting to the pressing of salicylates was that he found them bad for the rheumatic nervous child. He did not dispute their value for adult arthritis and for the relief of pain, but for cardiac cases in children he preferred the ethyl ester of para-methyl cinchonic acid.—Dr. Askins, in replying, expressed himself strongly in favour of cardiac clinics after his four years' experience in Bristol. They needed experts with great experience of heart cases to deal with these children satisfactorily.

SECTION OF PUBLIC MEDICINE.

Thursday, July 23rd.

Food Manipulation in Relation to Health.

A discussion on this subject was held under the presidency of Dr. T. E. Hill. Dr. William G. Savage, in the opening paper, said we could conveniently divide the effects of food manipulation into three groups, according to whether (i.) it affected the nutritive value of the food, or (ii.) produced bacterial or parasitic infections, or (iii.) resulted in chemical contamination. As regards (i.) he wished to protest against the views expressed by extremists. For example, he was much impressed with the importance of vitamins in our dietary, but he did not believe in advocating vitamins on grounds which we could not substantiate. As regards bacterial contamination of food, while dust or air-borne sources may be considerable, pathogenic bacilli were far more likely to be added from direct human handling. Great importance should be attached to the use of food which is sound initially. For example, *Bacillus botulinus* would find a suitable nidus for multiplication on or within damaged fruit and might produce a considerable amount of toxin. The danger of the survival of spores or even of toxin after heat-treatment was greatly increased by the use of damaged fruit or other food. It was important to classify the risks to health from manipulated food. Manipulated foods could be grouped according to the danger inherent in each different sort. In the first group came foods which were non-multiplying media for bacteria, and which were only eaten when cooked, such as ordinary cereals, rice, oatmeal, &c. In the next least dangerous group were non-multiplying media which were not subsequently cooked, such as bread. A third group contained foods which were multiplying media for bacteria, which were not subject to slow cooling, and which were subsequently cooked. Sausages were a good example. Sausages often contained numerous living bacilli and, being frequently only lightly cooked, a good many of the bacilli might survive. Sausages therefore should be well cooked, especially the German types of sausages containing blood, for these were more liable to harbour pathogenic organisms. In the fourth group came food which was a multiplying medium, was heated in its preparation, and subsequently cooled slowly, and then eaten without further cooking. If a food-poisoning bacillus gained access to such food when cooling, the temperature conditions favoured rapid multiplication. Many outbreaks of food poisoning had originated from this group, which included brawn, potted meats, and meat pies. In the most dangerous group were foods similar to the latter type, but containing viscera, and since pathogenic bacilli were more likely to be present in livers, lungs, and intestines, their preparation required special care. Fortunately these types of food were not greatly favoured in this country.

The following table showed the kind of food incriminated in 203 outbreaks of food poisoning in the British Isles, many of which were investigated by Mr. Bruce White, pathologist to the Home Office, and himself.

	Number and percentage.
Canned meat ..	31 (30·5)
" marine products ..	27
" fruit ..	4
Milk	14 (6·9)
Milk products ..	16 (7·9)
Made-up meat ..	61 (30·0
Manipulated meat	10 (4·9)
Fresh meat.. ..	33 (16·3)
Fruit and vegetables (not canned)	8 (3·9)
Other foods	6 (2·9)

As regards chemical contaminations, all preservatives except those scheduled as permissible should be prohibited, and the use of all permissible preservatives should be adequately declared on the label.

Dr. C. E. Goddard (M.O.H., Harrow-on-the-Hill) said it might be impossible to achieve perfect cleanliness, but it was incumbent on the public health service to prevent gross contamination. Imported food was a difficulty which might be dealt with by consular guarantees at the place of export. They had had recent revelations as to the conditions under which figs and sultanas were packed at Smyrna. He advocated the wrapping of bread. The M.O.H. had no power in the shops. He instanced the objectionable practice of customers pinching fruit, &c. Places where food is packed and made up should be licensed.

Dr. C. W. Cunnington said we needed more knowledge as to the effect of cold storage on the value of meat.

Dr. H. Scurfield agreed with Dr. Savage as to the tendency in some quarters to make exaggerated statements. He also deprecated the misleading loose general statements which were frequently made, even by those engaged in research work on this subject. He would like to see more work done to determine the vitamin content of such common foods as jam and marmalade. He thought there was plenty of evidence of something wrong with our dietary in the universal prevalence of dental decay and constipation and in last year's poor recruiting statistics. We were surely on safe grounds, he said, in advocating more milk and dairy products, more fresh fruit, and vegetables.—Dr. Noy Scott asked how it was that people could eat decomposed food in the form of game with impunity.

Dr. F. E. Wynne (Sheffield) said that the British Medical Association should insist upon the notification of cases of food poisoning. Opportunities for investigation were frequently lost by the failure of medical men to notify. He deprecated the use of much-advertised proprietary articles of food which were frequently extreme examples of food manipulation and the nutritive content of which was extremely expensive. It was unfortunate that such articles of food achieved such wide advertisement by their use at many infant welfare centres.

Dr. Hill said they were liable to "stunts" in public health, but that it was important to get what good they could from them. The wrapping of bread, for instance, might not be very important in itself, but was a good object-lesson. He hoped that the new regulations for preservatives would be issued unmodified.

Reply.

Dr. Savage, in reply, said there was no evidence that putrid food caused outbreaks of food poisoning. Such outbreaks were due to contamination with specific bacteria. *Bacillus botulinus* was endemic in the soil of some parts of California, but with ordinary precautions of cleanliness and the use of sound food the danger was infinitesimal. The Loch Maree outbreak was the only one in this country which had been traced to *B. botulinus*.

THE INFLUENCE OF LIGHT ON HEALTH.

A discussion on the influence of sunlight and artificial lights on health was opened by Dr. Leonard Hill in an interesting and valuable paper indicating the present state of knowledge on the subject. At the outset he described the varying effects of rays according to their wave-length. Smoke pollution cut off the shorter rays. What with mist, cloud, smoke, glass windows, and clothes, city people got almost no exposure to ultra-violet rays during the winter, and while every effort should be made to prevent smoke pollution and to educate people to expose their skin to the sunlight, a great deal could be done by means of arc baths which should be installed not only in hospitals, but also in schools and public baths. A skilled attendant would be required, but arc baths were no more dangerous than a public swimming bath. Given a long-flame arc, taking 2½ to 3 kilo-watts, with white flame carbon poles, and a wire net screen a yard away from it, children could safely dance within one or two yards of the lamp for five minutes, nude save for a loin cloth. As acclimatisation came on and the skin browned the time could be lengthened to 10 or 15 minutes. Such baths once or twice a week would do much to maintain good health and prevent such diseases as rickets, tuberculosis, rheumatic fever, skin diseases, and catarrhs. If tungsten-cored carbons were used the ultra-violet intensity was greatly increased and the time of exposure could be reduced to a third or even less. Goggles must be worn to prevent conjunctivitis. A great many lamps were at present on the market and many were so weak in ultra-violet radiation as to be of little use. Some were quack instruments giving only violet light. Ultra-violet radiation had power to cure many resistant skin diseases such as ichthyosis, psoriasis, eczema, and boils, and marasmic and delicate children were improved by it, and mothers who could not nurse their babies might be made more efficient. Some observers reported good results from the combination of red light and ultra-violet rays. The action of ultra-violet rays was not interfered with by ordinary daylight, therefore one could have the arc lamps in light rooms with the windows open. Febrile cases should be treated by light with very great caution. The hospitals of the future should be bungalows with open-air wards, verandahs, and unroofed open-air courts, about which the beds could be run according to the weather. Girls wearing open-necked blouses and short skirts with artificial silk stockings secured more ultra-violet radiation. Men would do well to alter their dress and get rid of the close collar and long trousers. While exposure to the lower part of the leg to light and cool air was a preventive of varicose veins, over-exposure in cold winter weather might produce a chilblain-like erythema. Physiological knowledge as well as fashion should rule dress and prevent both over- and under-exposure. There was no evidence that radiation could endow an inactive food with the growth qualities pertaining to vitamin A. The reaction of the skin appeared to have the same curative effect, whether produced by the mercury vapour, the white flame carbon arc, the Tungsten arc, or the Tungsten filament incandescent lamp with quartz globe. One clinician preferred lamps weak in ultra-violet rays and strong in heating effect with long exposures five days a week. Another used lamps powerful in ultra-violet rays with short exposures once or twice a week; one liked to produce a mild erythema; another avoided erythema. One liked to produce pigmentation; another thought pigmenting should be avoided. The need of the moment was to standardise the lamps for treatment and to find out the most economical methods of exposure. Dosage could easily be measured by the effect of ultra-violet radiation on the 30 per cent. acetone methylene-blue solution. Any loosely-woven garment let these rays through, but artificial silk fibre, being an acetyl-cellulose product, was more transparent than protein products, such as silk and wool fibres. If modesty required such material to be worn, longer exposures were needed. It had been stated that artificial sun treatment could not approach the real article. Dr. Hill's experience, however, was that properly regulated arc-light baths, with advice as to exposure to the open air, exercise, and diet, could effect cures in London which appeared to be no less good than those reported from Alpine sanatoriums. In order to eliminate tuberculosis from cattle similar exposure to light and air should be secured. Cattle as well as children might be given arc-light baths in the winter. Cattle also needed food rich in vitamin A during the winter and calcium to compensate the drain caused by heavy milking. Vitaglass, which allowed the ultra-violet rays to pass through, might have a use for verandahs and skylights.

Dr. G. B. Dixon (Tuberculosis M.O., Birmingham) said he had obtained good results in many forms of tuberculosis from the general light bath. Cases of lupus did well. Enlarged cervical glands first grew bigger and then gradually disappeared. Cases of hilus tuberculosis did well. Some bone and joint cases did well, while hip, sacro-iliac, and spinal cases did not, in his experience, show such good results. The tone of the muscles improved greatly under treatment. Non-pigmenters had to be treated more carefully. In some bone and joint cases with concurrent pulmonary disease the improvement in the bone or joint condition had taken place without the pulmonary lesion becoming worse.

Dr. Dora Colebrook gave her experiences of light treatment at the Islington centre. Small babies suffering from dietetic trouble did very well. Flabby muscles were toned up. In cases of malnutrition and vomiting the vomiting often ceased. There was an increase in vigour and brightness. Relapses after the cessation of treatment indicated success and the need for more continuous treatment. She believed in short courses of short exposures and found the treatment useful for nursing mothers. There was a distinct place for light treatment at infant welfare centres. She hoped that other centres would try the treatment and keep faithful records of the results obtained.

Dr. A. Eidenow said that many chronic fibroid pulmonary cases did extraordinarily well under light treatment. Infants and adults differed in their need of light. Beneficial effects were secured in very many resistant skin diseases, such as psoriasis and eczema. In the case of bone-tubercle, radiograms showed that there was increased calcification and density of the bone as the result of light treatment.

BAN ON POOR-LAW BUILDING.—The Minister of Health has refused to sanction the scheme of the Kensington Guardians for the enlargement of the X ray department and the erection of a new nurses' home at Kensington Infirmary. Mr. Neville Chamberlain declines to regard the plan as urgent, and adds that "in view of the scarcity of skilled labour available for housing schemes, and the uncertainty as to the future of the Poor-law generally, it is considered that all Poor-law building work which is not immediately necessary should be postponed."

SUSSEX PROVIDENT SCHEME. — The following amounts have just been paid to the institutions named for services rendered to subscribers of the Sussex Provident Scheme during the first six months of this year: Royal Sussex County Hospital, £1540; Royal Alexandra Hospital for Sick Children, £340; New Sussex Hospital, £325; Brighton, Hove, and Preston Dispensary, £150; Haywards Heath Hospital, £135; Sussex Eye Hospital, £115; Sussex Maternity and Women's Hospital, £105; Sussex Throat and Ear Hospital, £105; Brighton, Hove, and Preston Dental Hospital, £65; Uckfield Cottage Hospital, £50; Stephen Ralli Memorial Laboratory at the Royal Sussex County Hospital, £10; and Royal East Sussex Hospital, Hastings, £5. These sums make a total of £2945 for the half year. For the whole year of 1924 the amount distributed among the hospitals was £5320.

Reviews and Notices of Books.

SURGERY.

Practical Surgery Illustrated. By VICTOR PAUCHET. Translated by F. R. B. ATKINSON, M.D., C.M. Edin. With an introduction by Sir CHARLES GORDON-WATSON, C.M.G., F.R.C.S. Vols. V. and VI. London: Ernest Benn, Ltd. 1925. 18s. 6d. per volume.

THESE two volumes complete the English edition of Pauchet's atlas. Like the former parts, the drawings are unique in their clarity and depict the most varied procedures. In Vol. V. de Martel describes the operation for trigeminal neuralgia. The rest of the book is by the author, except Chapter IX. on the treatment of large scrotal hernia, which has been drawn up by A. Buquet. Pauchet's chief work lies in the abdomen, and his conclusions and remarks on the conditions delineated are interesting and full of suggestion. Some of his results are remarkable. He has implanted into the duodenum, with success, a persistent biliary sinus resulting from cholecystectomy, the patient being well 15 years later. In two other cases the common bile-duct was repaired around a tube and the patients are well seven and nine years after it. The author is at his best in describing gastric operations, of which he is a master. Another extremely good section is that dealing with carcinoma of the colon. In Vol. VI. different aspects of these two subjects are again brought in review. The operation for fistula in ano is described, the inguinal operation for femoral hernia, removal of a ureteric calculus, and some gynæcological procedures. The work now completed makes no pretension to be a complete treatise on operative surgery, of which many departments remain untouched, but the discriminating surgeon will find the book profoundly interesting and will lay it down with a sense of having profited by its perusal.

Die Chirurgie. By Prof. Dr. M. KIRSCHNER and Prof. Dr. O. NORDMANN. Berlin: Urban and Schwartzenberg. 1925. Vol. I., 18 marks; Vol. II., 18 marks.

A System of Surgery by a number of German-speaking contributors is appearing under the general editorship of Profs. Kirschner and Nordmann. Two volumes of this system are now before us. The first begins with an historical account, necessarily in bare outline, of the development of surgery, which will prove useful for its very complete bibliography. General and local anæsthetic methods are next discussed, followed by a section on antiseptic and aseptic methods. These chapters lose somewhat by compression; the English reader would have been glad to learn more of the local anæsthetic methods in vogue, for instance, and only one way of sterilising catgut is described. On the other hand, the chapter on the use of X rays and radium in surgery contains just what the general surgeon desires to know, and a well-balanced view of the therapeutic value of these agents is given. An account of X ray burns is included. The last chapter in this volume deals with constitution in relation to disease, an unfamiliar section to the English reader and worth perusal. The second volume, which is concerned with the surgery of the lymphatic glands, breast, thyroid, thymus, adrenals, and hypophysis, leaves little to be desired. The accounts of the diseases treated are systematic, straightforward, and conform to generally accepted ideas. The chapter on the breast contains a very complete set of illustrations of normal and morbid anatomy.

So far as it goes at present this System of Surgery can be cordially recommended to the English reader. Not the least of its merits is that it is essentially German in its outlook. To see things from the standpoint of an entirely different school of surgery is always profitable. Thus we find matters over which there is controversy in this country regarded in quite a different light in this book. For instance, fibro-adenoma of the breast is classified amongst the epithelial tumours, and the statement is made that it more easily changes into a carcinoma than a sarcoma. Carcinoma of the breast is accepted as spreading by the venous path at a certain stage of the disease. A number of statements will make the English student speculate upon the basis for his accepted beliefs. The standard of writing is high and the illustrations are admirable.

Chirurgische Propädeutik. By Prof. Dr. Erich Sonntag. Leipzig: George Thieme. 1925. Pp. 260. R.m. 0.60.

This book is for the use of students just beginning their clinical work. The author intends it to give instruction in those methods of examination which can be carried out with the unaided senses. So the book is divided up into sections which deal with the interrogation of the patient, inspection, palpation, auscultation, smelling, and measuring. Each section is divided into a general and a special part. Elementary methods of diagnosis are notoriously difficult to teach to the novice, and instruction of this kind is best given practically in the wards. Owing to the arrangement followed in this book, the students would have to refer to several sections if he desired to know how to examine, for instance, a tumour of the breast. Nevertheless, methods of clinical examination, as far as it is possible to impart such knowledge by the written word, are well described, and the illustrations are helpful.

CLINICAL PATHOLOGY.

Serum Diagnosis of Syphilis by Precipitation. By R. L. Kahn. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1925. Pp. 237. 15s.

In this book the author gives an account of the precipitive test he has devised for the diagnosis of syphilis. The complicated technique required in the Wassermann test has stimulated many workers to produce a simpler test. So far a certain amount of success has been obtained by the precipitive methods based on the works of Klausner, Sachs Georgi, and others. The test depends on the fact that when syphilitic serum is mixed with the ordinary Wassermann antigen, or with a special antigen, a fine precipitate is formed. In the Kahn test for syphilis detailed in this monograph very careful standardisation of all the ingredients is performed as a preliminary to the main test. In fact, so numerous are these standardisations that it is doubtful if the Kahn test can be considered to be any less complicated than the Wassermann test itself—except for the fact that there is in the test one less variable factor, the complement. The test can be used for cerebro-spinal fluid as well as blood. Details are given of comparative tests against the Wassermann reaction, in which the test came out well, but it will, of course, take years before the real value and reliability of the test can be determined. This volume is chiefly intended as a technical manual for laboratory workers and as such gives an admirable account of the test and the technique employed.

The Cerebro-spinal Fluid in Clinical Diagnosis. By J. Godwin Greenfield, M.D., B.Sc., M.R.C.P., Pathologist to the National Hospital for the Paralysed and Epileptic; and E. Arnold Carmichael, M.B., Ch.B., Resident Medical Officer, National Hospital for the Paralysed and Epileptic. London: Macmillan and Co., Ltd. 1925. Pp. 272. 12s.

The need of an authoritative work in English upon this subject has now been supplied. The book before us opens with a very detailed and satisfactory account of the technique of the operations of lumbar, cisternal, and ventricular punctures. The anatomy of the membranes of the brain and cord and the physiology of the cerebro-spinal fluid are competently dealt with in Chapter II. To the laboratory worker the section on technique will prove particularly useful.

The authors lay great stress upon their indebtedness to the work of Westrezat, and it is true that no one working upon the changes undergone by the cerebro-spinal fluid in disease can fail to recognise this debt. Perusal of the book, however, makes it evident that it contains few, possibly no statements the truth of which has not been actually tested by the authors themselves, and a good deal of the value of the book depends upon their own original observations. There are a number of long-recorded observations the value of which has escaped recognition and the authors do good service merely in drawing attention to them. Such a hitherto rather neglected observation is the lowering of the chlorides in the cerebro-spinal fluid in tuberculous meningitis. That this is the first and for a time may be the only sign of tuberculous invasion of the meninges is a fact that has hitherto escaped the attention it deserves. In dealing with the glucose content of the cerebro-spinal fluid the authors seem to overlook the wide fluctuations undergone by this substance in the blood under normal conditions.

This is a work which will make a wide appeal; it contains much matter of the utmost importance to medical men, whether in practice or working in the laboratory, hitherto only available in a foreign language or scattered through the pages of periodicals and proceedings. The authors have arranged their matter so that both the clinician and the laboratory worker can readily find exactly what they want.

PREMATERNITY.

Candid Counsels to Expectant Mothers. By Florence Stacpoole. London: A. and C. Black, Ltd. 1925. Pp. 173. 3s. 6d.

This book has been written for young or expectant mothers, especially those of the educated classes, by a lecturer to the National Health Society of London who knows her subject thoroughly and writes on it convincingly and well. The four sections of the book deal adequately with: Care of the health during pregnancy; care of the health during confinement; care of the health after confinement; care of the new-born infant. Short appendices contain information on the preparation to be made for the baby's arrival, twilight sleep, birth control, and the method suggested recently by Prof. Louise McIlroy of oiling the baby in lieu of washing it with soap and water during the first nine days after birth. The author's style is chatty, but the book is pleasant to read. Some misgiving may be felt as to the wisdom of including in a book written for mothers so many prescriptions—e.g., a diarrhœa mixture containing laudanum and several mixtures for indigestion—but apart from this we have nothing but praise for a guide-book which should command a wide circulation among nurses and expectant mothers.

Approaching Motherhood. By George L. Brodhead, M.D. New York: Paul B. Hoeber. 1925. Pp. 193. $1.25.

The purpose of this book is to answer some of the questions which most women approaching motherhood are likely to ask. The contents are therefore arranged in the form of question and answer, the range of subjects discussed covering the period from pregnancy to the puerperium. Some of the sections are extremely short and sketchy, such as that on the anatomy of the female genital tract, which is discussed in less than 60 lines. The chapter on popular fallacies deals with only four fallacies, one of which—"that it is dangerous to raise the arms above the head for fear of causing a knot in the cord"—we do not recollect having come across; another, "that pregnant women have what is known as cravings," is a fact and not a fallacy at all. Some of the points raised are trivial—e.g., Do babies ever weigh 15 pounds? Is the theatre harmful? Am I carrying high or low? do not appear to be particularly helpful. And on one or two points the author is in disagreement with accepted views in this country, when he urges, for instance, that the "comparatively small and harmless operation" of circumcision shall be performed on every boy within two weeks of birth; or that a baby should have its mouth swabbed out with cotton and boric acid at the time of the daily bath. The book is written in plain and simple language.

CHILD WELFARE.

The International Year Book of Child Care and Protection. Second edition. Compiled from official sources by EDWARD FULLER. London: Longmans, Green and Co.. and *The World's Children*, Ltd. 1925. Pp. 565. *7s. 6d.*

THE new edition of this year-book is expanded and improved. Opportunity has been taken to revise the tables and a hundred or more of the sections have been practically rewritten. The "Who's Who" section has, we are glad to see, been omitted, its place being taken by an international bibliography of books and periodicals published during 1924 on child care and protection. Dr. W. M. Feldman has contributed a chapter on Hebrew law in relation to children, and the index has been amplified. Mr. Fuller, who is editor of the *World's Children*, remarks how little one-half of the world knows even yet as to how the other half lives, and the primary object of the year-book is to help the peoples of the world to a better understanding of the things which concern the life and care of its children. As a compiler, he has been embarrassed by the lack of common standards in making statistics and classifying facts. Even in England the legal definition of "infant" is not commensurate with the accepted use of the term, and disparities of this nature vitiate comparisons which might usefully be made. The year-book is one more plea among many for reform in the demography of child welfare. Mr. Fuller's book in its new guise will usefully serve the interests of children in many countries.

LEGAL MEDICINE.

For Members of the Legal Profession and Police Forces. First edition. By JOHN GLAISTER, Junr., M.B., Ch.B. Glasg., Assistant to the Professor of Forensic Medicine, University of Glasgow; Lecturer on Medical Jurisprudence to the Glasgow Police Force. Glasgow: Alexander Stenhouse. 1925. With 4 illustrations. Pp. 158. *5s.*

LEGAL medicine is approached from very different angles by the doctor, the lawyer, and the police officer. Points which may appear of great importance to the medical man may be of secondary significance to counsel conducting a prosecution or a defence. The police officer is concerned with the tracking of the criminal and collecting all the available evidence, whilst the lawyer sifts this evidence in order to present his case. Dr. Glaister has attempted to put to members of the legal profession and to the police force the medical point of view, and to illustrate the working of the medical mind when medico-legal problems are involved. He has also set out the difficulties with which the doctor has to contend and the dangers of dogmatic statements. The book appears to be the outcome of lectures to the police force at Glasgow, and as such forms an excellent manual for their guidance, especially in the direction of enabling the police. whether by action or inaction, materially to assist the medical man in his duties. Dr. Glaister discusses the signs of drunkenness, describing pupillary reactions, and gives differential points for the diagnosis of a fit. The police officer should, of course, regard every case as serious until the surgeon has given his opinion, and the risk lest a little learning should lead the police officer to make rash diagnoses is, we think, very small. To the lawyer the work is more limited in its usefulness. It may enable him to appreciate rapidly the significance of many medical conditions of criminal import, but where a prosecution or a defence involves more detailed consideration he will need to consult a larger text-book. Dr. Glaister, however, finds space to discuss in detail several classical criminal cases, aptly making his points from the lessons learned in these cases.

The book is simply and clearly written and the author has collected much practical information into a small space.

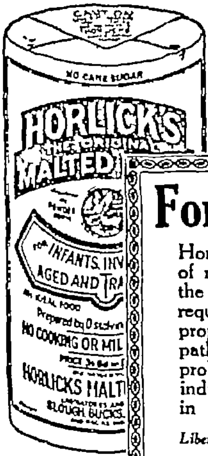
CHAMBERS'S ENCYCLOPÆDIA.

A Dictionary of Universal Knowledge. Edited by DAVID PATRICK, LL.D., and WILLIAM GEDDIE, M.A., B.Sc. Vol. III., Cata to Diop. Vol. IV., Diop. to Frei. Vol. V., Frej. to Humb. Vol. VI., Hume to Man. London: Chambers's. 1925. *20s.* per vol.

THIS encyclopædia is large enough to furnish an adequate outline of any subject referred to without being too bulky to fit into an average study library. The style of printing is attractive—the title of each article standing out in bold type; the information is concise and accurate and for the most part up to date. In some of the more technical articles where recent discoveries have altered the whole aspect of the subject, the addition of new paragraphs hardly meets the situation and an entirely new article is called for. The article on Embryology, for example, in Vol. IV. contains many references to work which is not now the last word on this rapidly growing subject. In Vol. VI. the historical account of the development of the University of London well explains the anomalies of the present organisation, while the description of the foundation of activities of the League of Nations, including its important health sections, is excellent. Indeed, it is impossible to turn over the pages of these volumes without being arrested by a title, an engraving, or a map which suggests a new point of view, or makes clearer the panorama from an old one.

JOURNALS.

INDIAN JOURNAL OF MEDICAL RESEARCH. April, 1925.—This number is of special interest. E. D. W. Greig and S. Kundu contribute three papers on Kala-azar, in one of which they compare the effect of treatment with various recently prepared antimony compounds, such as urea-stibamine and stibamine glucoside.—J. A. Sinton continues his series of studies on the Indian Species of Phlebotomus, paying attention to *P. argentipes*, the species recently suspected as being the vector of kala-azar, while R. B. Lloyd. L. E. Napier, and R. O. A. Smith have studied the blood meal of this insect identified by precipitin antisera, from which it appears that the insect feeds on the blood of cows in preference to that of man; the inference is drawn that the distribution of this disease observed in India is dependent on the absence of these animals from certain districts.—J. Cunningham and S. R. Pundit describe a new endemic focus of kala-azar in Southern India, L. E. Napier the environment associated with its prevalence in Calcutta.—U. N. Brahmachari and B. B. Maity continue their studies on the Chemotherapy of Antimonial Compounds.—M. J. Parmanand contributes the second part of his studies on the organism of rat-bite fever.—L. A. P. Anderson, A. Howard, and J. L. Simonsen have made important observations on the ætiology of lathyrism in India. The number also contains the eleventh section of W. F. Harvey's "bacteriological and laboratory technique."



For Infant Feeding

Horlick's Malted Milk—the Original—supplies all the elements of nutrition in Cereals and Milk in proper proportions and with the amylolytic conversion of starch, thus fulfilling the physiological requirements of Infants and constituting the characteristics of a proper diet in Infancy. It is dependable in all climates, free from pathogenic organisms, and affords a solution to the pure milk problem, as well as the prevention of those diseases often induced by amylaceous foods. Complete in itself and ready in a moment by briskly stirring the powder in water only.

THE LANCET.

LONDON: SATURDAY, AUGUST 15, 1925.

VOLUNTARY HOSPITAL ACCOMMODATION.

SOME four years ago when, particularly as an aftermath of the war and generally as a result of social changes, the whole voluntary hospital system in this country was ailing, the Government provided a stimulating draught of £500,000 to be administered pro rata to institutions which showed a readiness to help in their own cure. The distribution of this sum was entrusted to a Voluntary Hospitals Commission appointed in 1921.[1] This is the point chosen here to begin comment on a long story. The Commission accomplished their task with what must have been unhoped-for success, considering its nature, and then undertook, in April, 1924, at the instance of Mr. WHEATLEY, then Minister of Health, "to inquire into and report upon the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it." The report on this work, which has just been issued,[2] is a record of valuable and painstaking labours, and the information obtained sets forth a proof of the vitality of the voluntary system and of its hold upon the country

It might have been an easy matter to erect ideal standards of hospital accommodation without regard for time or money, but the Commission have left such ideals alone, concentrating upon the consideration of such extensions as were immediately necessary, and such, which is more, as were capable of accomplishment within a reasonable period. The careful study of the answers to questionnaires sent out to all the voluntary hospitals through the local voluntary hospital committees, wherein all the facilities for the institutional treatment of disease in each locality were collated, has made it possible for the Commission to formulate practical and valuable propositions for the solution of many sides of a complicated problem. The accommodation of our voluntary hospitals, as everyone knows, is at present inadequate to the needs of the people; the inclusion in any estimate of all the subsidiary accommodation provided by cottage hospitals, and convalescent and recovery homes still leaves it badly short, while the Poor-law infirmaries remain only potential adjuvants. It is of interest to note that the data furnished by hospital waiting-lists proved, on close inspection, to be an unreliable basis for assessment. It was found, for example, that maternity cases for which beds had been booked weeks or months in advance were sometimes included in the waiting-list figures, while on the other hand a notable shortness of the list in an area where the accommodation was obviously inadequate might be explained by the reluctance of medical practitioners to enter the names of patients whose chances of admission were merely problematical. With regard to coöperation with Poor-law infirmaries, the report states that astonishing differences were found in the attitude of different areas towards Poor-law institutions. The majority of local committees were unfavourable to coöperation; when schemes of mass contribution are in existence, it appears that the public regard any plan for coöperation with Poor-law infirmaries as an attempt on the part of the voluntary hospitals to escape an implied bargain; further, in many parts of the country prospective patients have strong prejudices against Poor-law beds. On the other hand, however, from a careful inspection the important fact emerged that the number of vacant beds in institutions at all comparable with voluntary hospitals was much smaller than was commonly supposed. If Poor-law hospitals are to be conscripted for further service, their function, it would seem, must be differentiated from that of the voluntary hospital; those who know more than the surface of the matter will not be surprised to learn that the filling-up of the infirmaries with the surplus sick is not the prompt remedy that many speakers have told us. The Commissioners suggest that the larger voluntary hospitals be reserved for cases requiring special diagnostic facilities or a high degree of technical skill, while the local authorities' hospitals should deal with patients whose primary need is skilled nursing. In allocating the many gradations between these two types of case requiring treatment, individual and local considerations would be the deciding factor in the choice of institution. The patient suffering from surgical tuberculosis, for whom the local authority has a statutory responsibility, has been indicted as the cause of much present pressure on voluntary hospital beds. The Commission believe that if local authorities undertook the provision of beds for all their cases, whether by paying the capital cost of any necessary hospital extension or, in the case of surgical tuberculosis, by adding surgical wards to existing sanatoriums, a considerable number of existing beds would be released for other cases. Many of the smaller hospitals, particularly the cottage hospitals, are at present not adequately used. In many instances this is due in large measure to difficulties in regard to suitable medical and surgical staff, and the Commission advocates the linking up of such institutions with the nearest big hospital. The future multiplication of cottage hospitals does not find favour with the Commissioners, who hold, also, that the extension of convalescent homes would do little to relieve in-patient pressure. But there is a considerable weight of opinion in favour of increasing the number of available recovery homes, a system which is as yet only in the experimental stage.

The outcome of the investigations of the Commission is that some 10,000 additional beds are required in England and Wales, including London. The actual figures submitted by local committees outside of London amounted in England to 9525 beds and in Wales to 1089 beds, or a total of 10,614 beds, and King Edward's Hospital Fund recommended an addition in London of 2088, but after careful consideration of the reports of the Commission's inspectors it was thought that that total figure might be reduced by about 20 per cent. The addition of 10,000 beds represents an increase of approximately 22 per cent. on the existing hospital accommodation. At present-day prices, excluding the cost of site, furniture, and equipment, it is estimated that a reasonable figure for the cost of extending plain buildings of a utilitarian character would be £400 per bed. This represents a formidable sum,[3] and the Commissioners find themselves forced, however, reluctantly, to the conclusion that a substantial measure of State aid is essential. There are many pitfalls to be avoided, as the report points out, in administering a State grant in order that, among other things, the voluntary principle may not be endangered, while needs and expenses vary in different localities. The proposal submitted by the Commission is therefore to allow a grant of 50 per cent. of the cost up to a maximum of £200 per bed, subject, of course, to the remaining 50 per cent. of the expenditure being raised locally or being available from existing building funds. It is further proposed that the task of formulating comprehensive schemes for local areas should devolve on the local committees of the voluntary hospitals. It may be that, in view of these extra duties, such committees will require extension and reorganisation, and to secure the fullest measure of effectivity the Commissioners do particularly urge the importance of full and frank conference with the medical staffs of the hospitals concerned. The Commissioners are prepared, if the Government see fit to accept their proposals, to act as a central body responsible for the distribution of this grant.

---

[1] THE LANCET, 1921, ii., 616.

[2] Ministry of Health. Voluntary Hospitals Commission Report on Voluntary Hospital Accommodation in England and Wales. H.M. Stationery Office. 1925.

We trust that the Government will come to the aid of the voluntary hospital system in the suggested way; for on all sides the improving prospect is admitted. Without the assistance and encouragement of the State there is in most cases little chance of essential extensions being undertaken within the next few years. Failure to meet the present needs of a growing population will not only entail a great amount of avoidable suffering, but it must also react to the prejudice of the voluntary system. There is no greater stimulus to subscribers, particularly to small subscribers whose regular support is essential to the solvency of voluntary hospitals, than the feeling that sufficient accommodation is provided to ensure reasonable hopes of admission. And it must be remembered that small subscribers, in the form of contributing patients, grow daily a greater financial asset.

◆

MIND AND BODY.

OF all concepts that most often to be used casually is among the least definable—namely, "mind." At the present time it has taken on a biological significance and expresses the life reaction of the entity which anatomically is represented by "the organism." No longer is mind regarded as a something essentially apart from body; psychology now moves hand in hand with physiology, though we are still far from making the relations definite. It is evident, however, that, though the central nervous system is essential for the function of mind, mental function involves much more than just that one system of the body.

Dr. JOSEPH SHAW BOLTON, for his recent Maudsley lecture, read before the Medico-Psychological Association,[1] chose as title Mind and Brain, and the matter and tone of his discourse throw into strong relief the controversy between the two opposing schools of mental research, the practical anatomists and the experimental psychologists. The lecturer belongs to the former and takes a determined stand on the facts that have been indisputably proved by years of patient anatomical labour. He regards the work of FREUD, McDOUGALL, and others who bring speculation and conjecture to elucidate their observations as an unfortunate and mischievous excrescence that so far from being of any service can only result in vitiating the work of men who, from their hard-won knowledge of the structure of the brain, are qualified to speak with authority on the nature of the mind. In the lecture he gives an able comparative survey of the anatomy and habits of insects, birds, and mammals, and includes sound comments on human psychology. Dr. BOLTON exposes the error that many habitually make of attributing human motives to lower animals; he shows that bees and ants have no kind of reason or sentiment to guide their collective labour, and that the behaviour of the trained bird is but an elaborate mechanical reaction. Both insects and birds have a rigid skeleton that has ensured their survival at the price of completely forbidding them to evolve further. He gives a detailed analysis of the brain measurements of a tomtit, a parrot, and a pheasant, showing that the cerebral pallium that gives the mammal its variety of function and capacity for further development is in all these representative birds a simple root to the lateral ventricle. He concludes from this that birds are merely elaborate machines, possessing neither mind nor a nervous mechanism for the evolution and performance of mental functions, a result certainly that it would be hard to controvert on the behalf of the many bird-lovers who claim for their pets an almost human intelligence. Dr. BOLTON sketches the development of mammals and shows that the growth of feeling and thought processes in higher animals like dogs and anthropoid apes depends entirely on the evolution of the highly complex cerebral pallium. His treatment of psychology—the disputed territory between himself and Prof. McDOUGALL, whom he quotes destructively throughout—is the climax of his lecture. He deals ably with language, voluntary thought, recorded experience, and recollection, the meaning of normal personality, of grades of cerebral activity, and of free association and dreams; after an analysis of feeling, and of the relative importance of education and the instincts, he considers mental disease, the best existing example of racial immaturity. He holds that the variety of mental deficiency and dementia amongst us indicates how slowly our minds evolve. "The greater the rapidity of evolution the more numerous the variations above and below the average—the more common must be individual genius and individual mental deficiency and dementia." Comparing human voluntary thought with the caricature of it seen in the lower animals, he holds that we are irresistibly impelled, "not to the idea that the lower animals think, but to the certainty that in the mass human beings do not."

Considering how valuable is Dr. BOLTON's insistence that truth must be sought by patient spade-work in the observation of facts, we regret the manner of his attacks on the concept of the "unconscious mind," and by implication of the spade-work of those observers who have invented and enlarged upon it. Truth is to be found by establishing facts, not by stating negatives—indeed, to quote Dr. BOLTON against himself, "even if many theories turn out to be false and many facts prove to be valueless, the individual who has produced them, so long as he has worked honestly, is the better for what he has done." Psychological function depends on brain structure, but brain anatomy is unintelligible unless the psychologists explain it. That function results in an extraordinary development of structural provision for possible future function the lecturer allows, and may it not be that the "unconscious mind" of the psychologists is the vague functioning of that unrelated structure of the brain pallium which stands ready to be specialised and developed as the human race moves forward towards its fulfilment? Truth at best is but a relative phenomenon, varying in its facets in accordance with the view-point of the observer. Considering the difficulty of the task in which workers in these fields are engaged, it is of the highest importance that every searcher for knowledge towards the understanding of life should realise that the truth may, nay must, be many-sided, and that, because his truth does not at once conform to another's, therefore the other is wrong. It is unfortunate that the broad view is so rarely to be found, but let us plead for a more concerted attack upon this most evasive of problems, seeking that the recognition of the usefulness of principles, whether psychological or physiological, be not obscured by the unbalanced and premature forcing of conclusions.

RHEUMATIC INFECTION IN CHILDHOOD.

From the point of view of public welfare few subjects could be found of greater importance than that of rheumatic infection in childhood, which was discussed at a joint meeting of the Sections of Diseases of Children and of Public Medicine at the annual meeting of the British Medical Association on July 22nd. The toll of human life from heart disease originating from this cause during the school age amounts, according to Dr. Robert A. Askins, of Bristol, to between 12,000 and 20,000 annually in England and Wales alone, whilst the hospitals have difficulty in finding accommodation for both the early cases and those suffering from serious sequelæ. A full account of this discussion will be found elsewhere in this issue, where it will be seen that practically all the speakers urged the need for speedy research into the many problems involved. Dr. F. J. Poynton, who has done great public service during many years in this respect, reiterated the necessity for closer inquiry concerning various ætiological factors, especially as regards home surroundings, the various modes of onset, the prevalence of chorea, and the importance of nervous over-strain among school-children. There appeared to be little doubt in the minds of the various speakers as to the infective nature of the disease; but many of them, including Dr. Robert Hutchison, the President, held strongly to the view that acute rheumatism cannot properly be described as a disease of slums, but is rather to be found amongst the children of the more well-to-do artisan class. This belief is borne out in an article by Dr. Vincent Coates and Dr. R. E. Thomas which we publish to-day. These observers have made careful clinical and ætiological inquiry concerning 50 cases selected at random from a much larger series of school-children seen during school inspection and at clinics. They find that in practically every case the parents of the affected children were in steady work and belonged to the skilled artisan section of society, the weekly gross income per head of the various families being from five to seven shillings in about 45 per cent. of cases and above this figure in the remainder. In a considerable number of cases the houses inhabited by the patients were damp, but overcrowding was notably absent. As regards treatment the most pressing need of the moment was considered by most speakers to be the establishment of more clinics for the care of such children, and the provision of institutions where long-continued rest could be properly obtained. The success of the Hartfield Hospital in Sussex has in this respect been very encouraging. In view of the drain on the life and wealth of the population which rheumatic fever and its consequences at present entail, expenditure on such establishments and on adequate research centres should be a sound national investment.

Annotations.

"Ne quid nimis."

THE MEMBERSHIP OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

We do not know if the significance of the amended By-law 112 of the College has been fully appreciated by our readers. The by-law now runs, "Every candidate for the Membership shall furnish proof of having attained the age of 23 years," whereas the age for admission to the examination for the diploma was formerly 25 years. This means that men of 23 years of age can now take the examination and gain the diploma without waiting for two years, by which time many of them have settled down into practice and have neither the time nor the inclination to submit themselves to an examination. Many men at 23 have just finished house appointments, and their examination knowledge having not yet faded, their recent clinical experience admirably fits them for the trial before them. In the past some men, who might have secured the M.R.C.P. had they been 25, have embarked on some special line of work, such as pathology or X rays, and so when they became eligible were both immersed in special work and lost touch with general medicine, and especially with the important branch of routine clinical examination. As time went on these men rose to eminence in their special branch of medicine, but were not eligible for the F.R.C.P. because they had not taken the M.R.C.P., and they and also the Royal College of Physicians of London were the losers. At the Royal College of Surgeons of England the final examination for the F.R.C.S. can be passed before the age of 25 years, while the successful candidate has to wait for the diploma until he attains that age. At the Royal College of Physicians of London this relaxation was not allowed.

AN HISTORICAL REVIEW OF PUBLIC HEALTH.

We print this week the fourth and last instalment of Dr. J. H. L. Cumpston's reflections on public health administration, provoked by a visit to America and England paid by him in his capacity of principal administrative health officer to the Commonwealth of Australia. Dr. Cumpston lays his finger on some weak points in administration which are largely the result of the haphazard way in which the whole structure has grown up. No doubt his kindly but trenchant criticism will be taken to heart by those concerned, and we propose in the next few weeks to provide further material for laying down sound principles of international hygiene by seeing how the various European countries have solved the problem in the light of careful studies made by the Health Bureau of the League of Nations.

During the present year several other senior members of the medical profession have written sketches of the motives and principles which have actuated public health progress. Sir Arthur Newsholme in his book emphasised the fundamental value of the crude dictum that the search for public health was a crusade against organic filth, though the value of personal hygiene is fully recognised in its pages and scientific work with educational effort to secure its application are urged. Prof. E. A. Winslow, of Yale, has stressed the personal side of public health work, the value of public health nursing, and of educational work. It is evident that only by a *vue toute ensemble* can the whole truth be encompassed. The sketch[1] now before us by a distinguished leader of the medical profession in America will prevent any too narrow view of the factors of reform which have preceded our present

condition. The occasion of the second annual Sedgwick lecture was utilised by Dr. W. H. Welch, of Baltimore, to review the pioneer work of this great American sanitarian. Dr. Welch contends that America's chief contribution to public health progress has been in the extended use of the laboratory as a means of control of disease; and the outstanding examples of this are the work of the Lawrence Experiment Station on water purification and the introduction by Hermann Biggs of laboratory diagnosis as a means of controlling infectious disease in New York. A more recent contribution of America to public health consists in its prohibition of the sale of alcoholic drinks, and it is not irrelevant to contrast this with Dr. Welch's reference to the compulsory control of a disease by diet as evidenced by the obligatory administration of lime-juice begun in the British Navy in 1796. The lecture brings out very lucidly the value of a working hypothesis in the advancement and application of knowledge, and the whole history of public health can be written around successive hypotheses on which action, more or less successful, has been based. In respect of tuberculosis we have the well entrenched older views of the constitutional element in tuberculosis, and on the other hand the remark of Koch, which Dr. Welch heard him make, that so far as tuberculosis is concerned "predisposition is merely proximity to the bacillus." Attention is drawn to the millions spent for the eradication of yellow fever, and wasted, under the influence of a wrong hypothesis as to its origin; and it is added "the same is largely true of typhus." This remark cannot be taken too literally, for from England typhus had been almost completely banished before its transmission by body lice, and probably in no other way, was suspected. The lecture is worthy of its author and will be read with interest by all. Dr. Welch rightly takes the view that courses of hygiene in the medical student's curriculum do not suffice; for there is no subject of medical study without some bearing on preventive medicine, and every teacher should consider it his duty to emphasise these aspects.

[1] Public Health in Theory and Practice: An Historical Review. By W. H. Welch, M.D., LL.D. Yale University Press. London: Oxford University Press. 4s. 6d.

DENTAL PROPAGANDA.

AT the May meeting of the Dental Board of the United Kingdom a good deal of time and thought were given to the subject of propaganda on the care of the teeth. Mr. F. Dyke Acland, the chairman of the Board, stated in his opening address that he was impressed by the amount of general good-will existing in many quarters towards the great object which the Dental Board had in view—namely, the improvement of the dental health of the nation. He expressed his belief that effective publicity might be attained without very considerable expenditure, if only it was properly directed and guided, and at a later stage in the proceedings the Board went on to allot a sum not exceeding £4000 during the present year for the purpose of propaganda. So far the publicity work of the Board has largely been in association with education and health authorities. During last year, for instance, more than 132,000 copies of a leaflet were distributed through 347 education authorities among teachers in primary and secondary schools; requests for dental films, including the popular "Tommy Tucker's Tooth," were received from 25 education and health authorities. But the Board, not content with this valuable educational work, set up an Advisory Committee with a view to working out the methods for a more general campaign. This Committee included representatives of the various dental associations, the Board of Education, the Food Education Society, the National Association of Insurance Committees, and of a number of manufacturers of dental supplies. The recommendations of this Advisory Committee, as presented to the Board, included the spending of a sum of £7000 in the first year on a scheme of press propaganda, the engagement of a journalist of suitable qualifications, and the envisaging of a campaign lasting three years at least. It is in this direction that some members of the dental profession, and those not the least influential, are feeling that the Board may be going a little too fast. An editorial article in the *British Dental Journal* for August regards the proposals with dislike, if not alarm, as an abandonment of the cherished tradition inculcated by the British Dental Association for nearly half a century—"*Thou shalt not advertise.*" In this article it is pointed out very forcibly how the "stunt game" is now so irrevocably associated in the public mind with some private interest lurking behind it, that the advertising pitch has been spoiled for orthodox professional play. The *Journal* is all in favour of propaganda through educational authorities, school teachers, medical officers of health, health societies, and the like, and sees in the education of parent and child in good dental habits, through the provision of good school dentistry, an agency for improvement without reproach. It is rather a piquant position for the dental profession, a section of which has in the past not been loth to use all available methods of publicity, now to be putting the brake on the Dental Board's proposed campaign of propaganda. We are in full sympathy with propaganda on the need for a healthy mouth, but we share the dislike felt by the *British Dental Journal* for a scheme of propaganda which entails extensive press publicity, the engagement of a special journalist, and a request for subsidies from the dental profession and the dental trade. With regard to the dental trade, we are sure that the best manufacturers concerned wish for no such publicity; and whatever its immediate success, the public will inevitably suspect in it a subtle way of increasing the income of the dental profession. It would, we believe, defeat its own end, and the *Journal* is probably right in thinking the scheme to be in the nature of a kite flown by the Board to test the feeling of the dental profession.

EYE SURGEON AND NURSE.

IT has often been said or implied that it is not the business of the nurse to know anything about the procedures which the surgeon may choose to adopt. But many surgeons have found that it is just such knowledge which is likely to increase her value, and certainly a theatre sister who does not know the uses of the instruments of which she has charge is likely to make mistakes which one who has familiarity with their use will avoid. For the nursing of eye cases a general training is not enough, and for operative work it is genuinely essential for the nurse to have expert guidance if she is to do justice to her patient. For these reasons we should like to commend a practical handbook[1] for the ophthalmic nurse which she cannot fail to find useful. This little book is evidently written by one who has had experience in the training of probationers in an eye hospital. It is neither too elementary nor is it prolix. Written in simple language, each chapter is of practical value and the illustrations are very clear. Just so much explanation of the anatomy of the eye is given as nurses need. Bandaging is well illustrated and a form of bandage described which, so far as we know, is peculiar to the Western Ophthalmic Hospital, where it is found to be very effective. After a chapter on the external diseases of the eye, which includes essential directions to the nurse in dealing with cases of contagious ophthalmia, she is introduced to the operating theatre, and the greater part of the book is taken up by an excellent description of her duties in the preparation of patients for operation, in the operating theatre itself, and during the after-treatment of operation cases. A useful chapter is appended on operations in a private house. In the section on local anæsthesia stress is properly laid on precautions against the roughening of the corneal epithelium that a careless instillation of cocaine causes. Exact directions are given for sterilising dressings, preparing swabs, and the sterilisation of sutures and

instruments. The directions for the after-treatment of cataract cases are full and include such points as how the nurse can help in a case of temporary retention of urine, and how best to arrange the bed-clothes for the patient's safety and comfort. Brief descriptions of the principal operations themselves are given.

---

[1] Ophthalmic Nursing. By Mary Mason Springgay, Matron of the Western Ophthalmic Hospital London. With 67 Illustrations. London: Methuen and Co. 1925. Pp. 133. 5s.

We believe that this little book supplies what many probationers in eye-wards have desired. "A nurse thoroughly interested in her work," the author writes, "should not automatically use drops or applications simply because they are ordered, but should closely watch their effect on the cases." This is sound doctrine.

THE CONGRESS OF THE ROYAL SANITARY INSTITUTE.

WE reported at some length in our issue of August 1st the proceedings at the Congress of the Royal Sanitary Institute in Edinburgh, and we are glad to learn that its promoters consider it one of the most successful gatherings which the Institute has held. Sir George Newman's address, sketching the future of sanitary administration along the lines of unification and enlargement of sanitary units, coördination of the health services, and increased health education, was supported by the resolution of the Representatives of Sanitary Authorities, on the motion of Lieut.-Colonel F. E. Fremantle, M.P., for a unified health service, and many speakers supported the call for further health education of the public. Edinburgh promotes this spirit of public instruction by placarding her tramway stations with electrically-lighted health notices—"The M.O.H. says 'Spitting causes Disease,'" and the like, while Dr. C. S. Thomson (M.O.H. Deptford) told how his authority had asked him to give lectures on their policies and procedures, which he had found well attended. Expression was often given in the meetings of the Institute to the new outlook of preventive medicine, which aims to-day less at the direct reduction of mortality, and more at the reduction of disabling disease and at securing increased health and exalted resistance for the individual. Future advances, it is becoming felt, will depend largely on individual citizens by whom patient attention must be given to the laws of health.

The next Congress of the Institute will mark the jubilee of the Institute, which was founded in 1876; the meeting will be held in London on July 5th to 10th, 1926, under the presidency of the Duke of Northumberland, the opening meeting taking place in the Guildhall and the sectional meetings at Westminster.

ANIMAL PATHOLOGY AND PHYSIOLOGY.

ORGANISED research into animal diseases has been sleepy in its progress, but there are signs of an awakening movement. During the past year the Ministry of Agriculture's laboratory, the Institute of Animal Pathology at Cambridge, and the Animal Diseases Research Association at Glasgow, have all been actively engaged in the elucidation of puzzling factors in creature maladies. Braxy in sheep has always exacted a heavy toll in some districts and a vaccine is now being employed successfully against it. In 52,000 sheep which were inoculated, the death-rate was only one-quarter of that in untreated sheep. Lamb dysentery is another well-established disease, and persists so obstinately on some farms that the rearing of lambs has had to be given up. Mr. S. H. Gaiger, F.R.C.V.S., considers that the organisms which produce it are all "soil bacteria" and that the disease does not occur in the uterus of the ewe before lambing. This theory has been tested during the 1925 season, and the statistics of the Wellcome Physiological Research Laboratories, Beckenham, seem to indicate that inoculation of pregnant ewes with antigens made from the organisms isolated from cases of the disease has produced a decrease in the lamb fatalities. Scrapie and trembling or louping ill, two distinct diseases of sheep, have also been investigated; but not much progress has been made with them, as both seem to be of obscure nervous origin and transmitted by tainted stock. Grass disease in horses and mammitis in cows and ewes have also received attention, and as time goes on much of the leeway in the domain of research in animal diseases will be gradually overhauled. The Institute of Animal Pathology has carried out a considerable number of routine examinations for veterinary surgeons during the year and is getting together a good library on animal diseases. Mr. W. A. Pool, M.R.C.V.S., late of the Indian Veterinary Service, has joined the research staff as senior research assistant. On the physiological side work has been no less interesting. The Rowett Research Institute, which was established as far back as 1912, near Aberdeen, for the study of animal nutrition, has issued a series of collected papers under the editorship of Dr. J. B. Orr, the director.[1] They cover a great variety of subjects, including the mineral metabolism of pigs and its relation to rickets; the respiratory exchange of goats; the water balance of the body; the nature of scrapie in sheep; the diet appropriate to the intensive raising of chickens; and many other topics of interest and importance. To anyone who likes browsing in a various collection of printed matter—and what genuine student does not?—the volume will make a strong appeal. It will remind him of the great difficulty of trying to keep track of any subject in the flood of present publications. For example, it is of obvious moment that those interested in respiration should consult the papers on the influence of external temperature, work, and pregnancy on the energy exchange of the goat. These, however, have not been published also in one of the physiological magazines, but only in the *Journal of Agricultural Science*, and we have to thank Dr. Orr for the dissemination of the information. We wish him and his colleagues all success in their second volume. Their work has a wider interest than the nutrition of farm animals.

THE NEW MILK AND DAIRIES REGULATIONS.

THE suspended Milk and Dairies (Consolidation) Act, 1915, will come into operation on Sept. 1st next. This Act repeals and re-enacts a number of provisions contained in the Contagious Diseases (Animals) Acts and the Sale of Food and Drugs Acts with regard to milk and dairies. It also reproduces a number of amendments and new provisions which were contained in the Milk and Dairies Act, 1914, the operation of which was deferred. Sections 1 and 2 extend the list of purposes for which Orders may be made under the Contagious Diseases (Animals) Act, 1878, and it is proposed as soon as possible to make an Order under the new powers. Sections 3, 4, and 5 contain provisions similar in effect to those contained in a number of local Acts for stopping the supply of milk likely to cause tuberculosis. Under the new Act the duty of enforcement is placed on the council of the county or county borough in which the cows are kept, and any Order made by them will prohibit the sale of the affected milk in any area. Section 4 requires the medical officer of health of the county or county borough to make the necessary investigations on receipt of a notice from any other medical officer of health. The Tuberculosis Order of 1925 providing for the slaughter of bovine animals affected with certain specified forms of tuberculosis and for the payment of compensation in respect of animals so slaughtered will come into operation on the same day as the Act, and it will be the duty of the local authority discovering the presence in a herd of a tuberculous animal to cause it to be slaughtered or to report the matter to the relevant authority for the appropriate action. Sections 6 and 7 re-enact provisions contained in the Sale of Food and Drugs Act, 1899. Section 8, in conjunction

condition. The occasion of the second annual Sedgwick lecture was utilised by Dr. W. H. Welch, of Baltimore, to review the pioneer work of this great American sanitarian. Dr. Welch contends that America's chief contribution to public health progress has been in the extended use of the laboratory as a means of control of disease; and the outstanding examples of this are the work of the Lawrence Experiment Station on water purification and the introduction by Hermann Biggs of laboratory diagnosis as a means of controlling infectious disease in New York. A more recent contribution of America to public health consists in its prohibition of the sale of alcoholic drinks, and it is not irrelevant to contrast this with Dr. Welch's reference to the compulsory control of a disease by diet as evidenced by the obligatory administration of lime-juice begun in the British Navy in 1796. The lecture brings out very lucidly the value of a working hypothesis in the advancement and application of knowledge, and the whole history of public health can be written around successive hypotheses on which action, more or less successful, has been based. In respect of tuberculosis we have the well entrenched older views of the constitutional element in tuberculosis, and on the other hand the remark of Koch, which Dr. Welch heard him make, that so far as tuberculosis is concerned "predisposition is merely proximity to the bacillus." Attention is drawn to the millions spent for the eradication of yellow fever, and wasted, under the influence of a wrong hypothesis as to its origin; and it is added "the same is largely true of typhus." This remark cannot be taken too literally, for from England typhus had been almost completely banished before its transmission by body lice, and probably in no other way, was suspected. The lecture is worthy of its author and will be read with interest by all. Dr. Welch rightly takes the view that courses of hygiene in the medical student's curriculum do not suffice; for there is no subject of medical study without some bearing on preventive medicine, and every teacher should consider it his duty to emphasise these aspects.

DENTAL PROPAGANDA.

AT the May meeting of the Dental Board of the United Kingdom a good deal of time and thought were given to the subject of propaganda on the care of the teeth. Mr. F. Dyke Acland, the chairman of the Board, stated in his opening address that he was impressed by the amount of general good-will existing in many quarters towards the great object which the Dental Board had in view—namely, the improvement of the dental health of the nation. He expressed his belief that effective publicity might be attained without very considerable expenditure, if only it was properly directed and guided, and at a later stage in the proceedings the Board went on to allot a sum not exceeding £4000 during the present year for the purpose of propaganda. So far the publicity work of the Board has largely been in association with education and health authorities. During last year, for instance, more than 132,000 copies of a leaflet were distributed through 347 education authorities among teachers in primary and secondary schools; requests for dental films, including the popular "Tommy Tucker's Tooth," were received from 25 education and health authorities. But the Board, not content with this valuable educational work, set up an Advisory Committee with a view to working out the methods for a more general campaign. This Committee included representatives of the various dental associations, the Board of Education, the Food Education Society, the National Association of Insurance Committees, and of a number of manufacturers of dental supplies. The recommendations of this Advisory Committee, as presented to the Board, included the spending of a sum of £7000 in the first year on a scheme of press propaganda, the engagement of a journalist of suitable qualifications, and the envisaging of a campaign lasting three years at least. It is in this direct on that some members of the dental profession, and those not the least influential, are feeling that the Board may be going a little too fast. An editorial article in the *British Dental Journal* for August regards the proposals with dislike, if not alarm, as an abandonment of the cherished tradition inculcated by the British Dental Association for nearly half a century—"Thou shalt not advertise." In this article it is pointed out very forcibly how the "stunt game" is now so irrevocably associated in the public mind with some private interest lurking behind it, that the advertising pitch has been spoiled for orthodox professional play. The *Journal* is all in favour of propaganda through educational authorities, school teachers, medical officers of health, health societies, and the like, and sees in the education of parent and child in good dental habits, through the provision of good school dentistry, an agency for improvement without reproach. It is rather a piquant position for the dental profession, a section of which has in the past not been loth to use all available methods of publicity, now to be putting the brake on the Dental Board's proposed campaign of propaganda. We are in full sympathy with propaganda on the need for a healthy mouth, but we share the dislike felt by the *British Dental Journal* for a scheme of propaganda which entails extensive press publicity, the engagement of a special journalist, and a request for subsidies from the dental profession and the dental trade. With regard to the dental trade, we are sure that the best manufacturers concerned wish for no such publicity; and whatever its immediate success, the public will inevitably suspect in it a subtle way of increasing the income of the dental profession. It would, we believe, defeat its own end, and the *Journal* is probably right in thinking the scheme to be in the nature of a kite flown by the Board to test the feeling of the dental profession.

EYE SURGEON AND NURSE.

IT has often been said or implied that it is not the business of the nurse to know anything about the procedures which the surgeon may choose to adopt. But many surgeons have found that it is just such knowledge which is likely to increase her value, and certainly a theatre sister who does not know the uses of the instruments of which she has charge is likely to make mistakes which one who has familiarity with their use will avoid. For the nursing of eye cases a general training is not enough, and for operative work it is genuinely essential for the nurse to have expert guidance if she is to do justice to her patient. For these reasons we should like to commend a practical handbook[1] for the ophthalmic nurse which she cannot fail to find useful. This little book is evidently written by one who has had experience in the training of probationers in an eye hospital. It is neither too elementary nor is it prolix. Written in simple language, each chapter is of practical value and the illustrations are very clear. Just so much explanation of the anatomy of the eye is given as nurses need. DENTAL PROPAGANDA.

AT the May meeting of the Dental Board of the United Kingdom a good deal of time and thought were given to the subject of propaganda on the care of the teeth. Mr. F. Dyke Acland, the chairman of the Board, stated in his opening address that he was impressed by the amount of general good-will existing in many quarters towards the great object which the Dental Board had in view—namely, the improvement of the dental health of the nation. He expressed his belief that effective publicity might be attained without very considerable expenditure, if only it was properly directed and guided, and at a later stage in the proceedings the Board went on to allot a sum not exceeding £4000 during the present year for the purpose of propaganda. So far the publicity work of the Board has largely been in association with education and health authorities. During last year, for instance, more than 132,000 copies of a leaflet were distributed through 347 education authorities among teachers in primary and secondary schools; requests for dental films, including the popular "Tommy Tucker's Tooth," were received from 25 education and health authorities. But the Board, not content with this valuable educational work, set up an Advisory Committee with a view to working out the methods for a more general campaign. This Committee included representatives of the various dental associations, the Board of Education, the Food Education Society, the National Association of Insurance Committees, and of a number of manufacturers of dental supplies. The recommendations of this Advisory Committee, as presented to the Board, included the spending of a sum of £7000 in the first year on a scheme of press propaganda, the engagement of a journalist of suitable qualifications, and the envisaging of a campaign lasting three years at least. It is in this direction that some members of the dental profession, and those not the least influential, are feeling that the Board may be going a little too fast. An editorial article in the *British Dental Journal* for August regards the proposals with dislike, if not alarm, as an abandonment of the cherished tradition inculcated by the British Dental Association for nearly half a century—"Thou shalt not advertise." In this article it is pointed out very forcibly how the "stunt game" is now so irrevocably associated in the public mind with some private interest lurking behind it, that the advertising pitch has been spoiled for orthodox professional play. The *Journal* is all in favour of propaganda through educational authorities, school teachers, medical officers of health, health societies, and the like, and sees in the education of parent and child in good dental habits, through the provision of good school dentistry, an agency for improvement without reproach. It is rather a piquant position for the dental profession, a section of which has in the past not been loth to use all available methods of publicity, now to be putting the brake on the Dental Board's proposed campaign of propaganda. We are in full sympathy with propaganda on the need for a healthy mouth, but we share the dislike felt by the *British Dental Journal* for a scheme of propaganda which entails extensive press publicity, the engagement of a special journalist, and a request for subsidies from the dental profession and the dental trade. With regard to the dental trade, we are sure that the best manufacturers concerned wish for no such publicity; and whatever its immediate success, the public will inevitably suspect in it a subtle way of increasing the income of the dental profession. It would, we believe, defeat its own end, and the *Journal* is probably right in thinking the scheme to be in the nature of a kite flown by the Board to test the feeling of the dental profession.

EYE SURGEON AND NURSE.

IT has often been said or implied that it is not the business of the nurse to know anything about the procedures which the surgeon may choose to adopt. But many surgeons have found that it is just such knowledge which is likely to increase her value, and certainly a theatre sister who does not know the uses of the instruments of which she has charge is likely to make mistakes which one who has familiarity with their use will avoid. For the nursing of eye cases a general training is not enough, and for operative work it is genuinely essential for the nurse to have expert guidance if she is to do justice to her patient. For these reasons we should like to commend a practical handbook[1] for the ophthalmic nurse which she cannot fail to find useful. This little book is evidently written by one who has had experience in the training of probationers in an eye hospital. It is neither too elementary nor is it prolix. Written in simple language, each chapter is of practical value and the illustrations are very clear. Just so much explanation of the anatomy of the eye is given as nurses need. Bandaging is well illustrated and a form of bandage described which, so far as we know, is peculiar to the Western Ophthalmic Hospital, where it is found to be very effective. After a chapter on the external diseases of the eye, which includes essential directions to the nurse in dealing with cases of contagious ophthalmia, she is introduced to the operating theatre, and the greater part of the book is taken up by an excellent description of her duties in the preparation of patients for operation, in the operating theatre itself, and during the after-treatment of operation cases. A useful chapter is appended on operations in a private house. In the section on local anæsthesia stress is properly laid on precautions against the roughening of the corneal epithelium that a careless instillation of cocaine causes. Exact directions are given for sterilising dressings, preparing swabs, and the sterilisation of sutures and

instruments. The directions for the after-treatment of cataract cases are full and include such points as how the nurse can help in a case of temporary retention of urine, and how best to arrange the bed-clothes for the patient's safety and comfort. Brief descriptions of the principal operations themselves are given.

---

[1] Ophthalmic Nursing. By Mary Mason Springgay, Matron of the Western Ophthalmic Hospital London. With 67 Illustrations. London: Methuen and Co. 1925. Pp. 133. 5s.

We believe that this little book supplies what many probationers in eye-wards have desired. "A nurse thoroughly interested in her work," the author writes, "should not automatically use drops or applications simply because they are ordered, but should closely watch their effect on the cases." This is sound doctrine.

THE CONGRESS OF THE ROYAL SANITARY INSTITUTE.

WE reported at some length in our issue of August 1st the proceedings at the Congress of the Royal Sanitary Institute in Edinburgh, and we are glad to learn that its promoters consider it one of the most successful gatherings which the Institute has held. Sir George Newman's address, sketching the future of sanitary administration along the lines of unification and enlargement of sanitary units, coördination of the health services, and increased health education, was supported by the resolution of the Representatives of Sanitary Authorities, on the motion of Lieut.-Colonel F. E. Fremantle, M.P., for a unified health service, and many speakers supported the call for further health education of the public. Edinburgh promotes this spirit of public instruction by placarding her tramway stations with electrically-lighted health notices—"The M.O.H. says 'Spitting causes Disease,'" and the like, while Dr. C. S. Thomson (M.O.H. Deptford) told how his authority had asked him to give lectures on their policies and procedures, which he had found well attended. Expression was often given in the meetings of the Institute to the new outlook of preventive medicine, which aims to-day less at the direct reduction of mortality, and more at the reduction of disabling disease and at securing increased health and exalted resistance for the individual. Future advances, it is becoming felt, will depend largely on individual citizens by whom patient attention must be given to the laws of health.

The next Congress of the Institute will mark the jubilee of the Institute, which was founded in 1876; the meeting will be held in London on July 5th to 10th, 1926, under the presidency of the Duke of Northumberland, the opening meeting taking place in the Guildhall and the sectional meetings at Westminster.

ANIMAL PATHOLOGY AND PHYSIOLOGY.

ORGANISED research into animal diseases has been sleepy in its progress, but there are signs of an awakening movement. During the past year the Ministry of Agriculture's laboratory, the Institute of Animal Pathology at Cambridge, and the Animal Diseases Research Association at Glasgow, have all been actively engaged in the elucidation of puzzling factors in creature maladies. Braxy in sheep has always exacted a heavy toll in some districts and a vaccine is now being employed successfully against it. In 52,000 sheep which were inoculated, the death-rate was only one-quarter of that in untreated sheep. Lamb dysentery is another well-established disease, and persists so obstinately on some farms that the rearing of lambs has had to be given up. Mr. S. H. Gaiger, F.R.C.V.S., considers that the organisms which produce it are all "soil bacteria" and that the disease does not occur in the uterus of the ewe before lambing. This theory has been tested during the 1925 season, and the statistics of the Wellcome Physiological Research Laboratories, Beckenham, seem to indicate that inoculation of pregnant ewes with antigens made from the organisms isolated from cases of the disease has produced a decrease in the lamb fatalities. Scrapie and trembling or louping ill, two distinct diseases of sheep, have also been investigated; but not much progress has been made with them, as both seem to be of obscure nervous origin and transmitted by tainted stock. Grass disease in horses and mammitis in cows and ewes have also received attention, and as time goes on much of the leeway in the domain of research in animal diseases will be gradually overhauled. The Institute of Animal Pathology has carried out a considerable number of routine examinations for veterinary surgeons during the year and is getting together a good library on animal diseases. Mr. W. A. Pool, M.R.C.V.S., late of the Indian Veterinary Service, has joined the research staff as senior research assistant. On the physiological side work has been no less interesting. The Rowett Research Institute, which was established as far back as 1912, near Aberdeen, for the study of animal nutrition, has issued a series of collected papers under the editorship of Dr. J. B. Orr, the director.[1] They cover a great variety of subjects, including the mineral metabolism of pigs and its relation to rickets; the respiratory exchange of goats; the water balance of the body; the nature of scrapie in sheep; the diet appropriate to the intensive raising of chickens; and many other topics of interest and importance. To anyone who likes browsing in a various collection of printed matter—and what genuine student does not?—the volume will make a strong appeal. It will remind him of the great difficulty of trying to keep track of any subject in the flood of present publications. For example, it is of obvious moment that those interested in respiration should consult the papers on the influence of external temperature, work, and pregnancy on the energy exchange of the goat. These, however, have not been published also in one of the physiological magazines, but only in the *Journal of Agricultural Science*, and we have to thank Dr. Orr for the dissemination of the information. We wish him and his colleagues all success in their second volume. Their work has a wider interest than the nutrition of farm animals.

THE NEW MILK AND DAIRIES REGULATIONS.

THE suspended Milk and Dairies (Consolidation) Act, 1915, will come into operation on Sept. 1st next. This Act repeals and re-enacts a number of provisions contained in the Contagious Diseases (Animals) Acts and the Sale of Food and Drugs Acts with regard to milk and dairies. It also reproduces a number of amendments and new provisions which were contained in the Milk and Dairies Act, 1914, the operation of which was deferred. Sections 1 and 2 extend the list of purposes for which Orders may be made under the Contagious Diseases (Animals) Act, 1878, and it is proposed as soon as possible to make an Order under the new powers. Sections 3, 4, and 5 contain provisions similar in effect to those contained in a number of local Acts for stopping the supply of milk likely to cause tuberculosis. Under the new Act the duty of enforcement is placed on the council of the county or county borough in which the cows are kept, and any Order made by them will prohibit the sale of the affected milk in any area. Section 4 requires the medical officer of health of the county or county borough to make the necessary investigations on receipt of a notice from any other medical officer of health. The Tuberculosis Order of 1925 providing for the slaughter of bovine animals affected with certain specified forms of tuberculosis and for the payment of compensation in respect of animals so slaughtered will come into operation on the same day as the Act, and it will be the duty of the local authority discovering the presence in a herd of a tuberculous animal to cause it to be slaughtered or to report the matter to the relevant authority for the appropriate action. Sections 6 and 7 re-enact provisions contained in the Sale of Food and Drugs Act, 1899. Section 8, in conjunction

condition. The occasion of the second annual Sedgwick lecture was utilised by Dr. W. H. Welch, of Baltimore, to review the pioneer work of this great American sanitarian. Dr. Welch contends that America's chief contribution to public health progress has been in the extended use of the laboratory as a means of control of disease; and the outstanding examples of this are the work of the Lawrence Experiment Station on water purification and the introduction by Hermann Biggs of laboratory diagnosis as a means of controlling infectious disease in New York. A more recent contribution of America to public health consists in its prohibition of the sale of alcoholic drinks, and it is not irrelevant to contrast this with Dr. Welch's reference to the compulsory control of a disease by diet as evidenced by the obligatory administration of lime-juice begun in the British Navy in 1796. The lecture brings out very lucidly the value of a working hypothesis in the advancement and application of knowledge, and the whole history of public health can be written around successive hypotheses on which action, more or less successful, has been based. In respect of tuberculosis we have the well entrenched older views of the constitutional element in tuberculosis, and on the other hand the remark of Koch, which Dr. Welch heard him make, that so far as tuberculosis is concerned "predisposition is merely proximity to the bacillus." Attention is drawn to the millions spent for the eradication of yellow fever, and wasted, under the influence of a wrong hypothesis as to its origin; and it is added "the same is largely true of typhus." This remark cannot be taken too literally, for from England typhus had been almost completely banished before its transmission by body lice, and probably in no other way, was suspected. The lecture is worthy of its author and will be read with interest by all. Dr. Welch rightly takes the view that courses of hygiene in the medical student's curriculum do not suffice; for there is no subject of medical study without some bearing on preventive medicine, and every teacher should consider it his duty to emphasise these aspects.

Price 21s.

DENTAL PROPAGANDA.

AT the May meeting of the Dental Board of the United Kingdom a good deal of time and thought were given to the subject of propaganda on the care of the teeth. Mr. F. Dyke Acland, the chairman of the Board, stated in his opening address that he was impressed by the amount of general good-will existing in many quarters towards the great object which the Dental Board had in view—namely, the improvement of the dental health of the nation. He expressed his belief that effective publicity might be attained without very considerable expenditure, if only it was properly directed and guided, and at a later stage in the proceedings the Board went on to allot a sum not exceeding £4000 during the present year for the purpose of propaganda. So far the publicity work of the Board has largely been in association with education and health authorities. During last year, for instance, more than 132,000 copies of a leaflet were distributed through 347 education authorities among teachers in primary and secondary schools; requests for dental films, including the popular "Tommy Tucker's Tooth," were received from 25 education and health authorities. But the Board, not content with this valuable educational work, set up an Advisory Committee with a view to working out the methods for a more general campaign. This Committee included representatives of the various dental associations, the Board of Education, the Food Education Society, the National Association of Insurance Committees, and of a number of manufacturers of dental supplies. The recommendations of this Advisory Committee, as presented to the Board, included the spending of a sum of £7000 in the first year on a scheme of press propaganda, the engagement of a journalist of suitable qualifications, and the envisaging of a campaign lasting three years at least. It is in this direction that some members of the dental profession, and those not the least influential, are feeling that the Board may be going a little too fast. An editorial article in the *British Dental Journal* for August regards the proposals with dislike, if not alarm, as an abandonment of the cherished tradition inculcated by the British Dental Association for nearly half a century—"Thou shalt not advertise." In this article it is pointed out very forcibly how the "stunt game" is now so irrevocably associated in the public mind with some private interest lurking behind it, that the advertising pitch has been spoiled for orthodox professional play. The *Journal* is all in favour of propaganda through educational authorities, school teachers, medical officers of health, health societies, and the like, and sees in the education of parent and child in good dental habits, through the provision of good school dentistry, an agency for improvement without reproach. It is rather a piquant position for the dental profession, a section of which has in the past not been loth to use all available methods of publicity, now to be putting the brake on the Dental Board's proposed campaign of propaganda. We are in full sympathy with propaganda on the need for a healthy mouth, but we share the dislike felt by the *British Dental Journal* for a scheme of propaganda which entails extensive press publicity, the engagement of a special journalist, and a request for subsidies from the dental profession and the dental trade. With regard to the dental trade, we are sure that the best manufacturers concerned wish for no such publicity; and whatever its immediate success, the public will inevitably suspect in it a subtle way of increasing the income of the dental profession. It would, we believe, defeat its own end, and the *Journal* is probably right in thinking the scheme to be in the nature of a kite flown by the Board to test the feeling of the dental profession.

EYE SURGEON AND NURSE.

IT has often been said or implied that it is not the business of the nurse to know anything about the procedures which the surgeon may choose to adopt. But many surgeons have found that it is just such knowledge which is likely to increase her value, and certainly a theatre sister who does not know the uses of the instruments of which she has charge is likely to make mistakes which one who has familiarity with their use will avoid. For the nursing of eye cases a general training is not enough, and for operative work it is genuinely essential for the nurse to have expert guidance if she is to do justice to her patient. For these reasons we should like to commend a practical handbook[1] for the ophthalmic nurse which she cannot fail to find useful. This little book is evidently written by one who has had experience in the training of probationers in an eye hospital. It is neither too elementary nor is it prolix. Written in simple language, each chapter is of practical value and the illustrations are very clear. Just so much explanation of the anatomy of the eye is given as nurses need. Bandaging is well illustrated and a form of bandage described which, so far as we know, is peculiar to the Western Ophthalmic Hospital, where it is found to be very effective. After a chapter on the external diseases of the eye, which includes essential directions to the nurse in dealing with cases of contagious ophthalmia, she is introduced to the operating theatre, and the greater part of the book is taken up by an excellent description of her duties in the preparation of patients for operation, in the operating theatre itself, and during the after-treatment of operation cases. A useful chapter is appended on operations in a private house. In the section on local anæsthesia stress is properly laid on precautions against the roughening of the corneal epithelium that a careless instillation of cocaine causes. Exact directions are given for sterilising dressings, preparing swabs, and the sterilisation of sutures and

instruments. The directions for the after-treatment of cataract cases are full and include such points as how the nurse can help in a case of temporary retention of urine, and how best to arrange the bed-clothes for the patient's safety and comfort. Brief descriptions of the principal operations themselves are given.

We believe that this little book supplies what many probationers in eye-wards have desired. "A nurse thoroughly interested in her work," the author writes, "should not automatically use drops or applications simply because they are ordered, but should closely watch their effect on the cases." This is sound doctrine.

THE CONGRESS OF THE ROYAL SANITARY *INSTITUTE.*

WE reported at some length in our issue of August 1st the proceedings at the Congress of the Royal Sanitary Institute in Edinburgh, and we are glad to learn that its promoters consider it one of the most successful gatherings which the Institute has held. Sir George Newman's address, sketching the future of sanitary administration along the lines of unification and enlargement of sanitary units, coördination of the health services, and increased health education, was supported by the resolution of the Representatives of Sanitary Authorities, on the motion of Lieut.-Colonel F. E. Fremantle, M.P., for a unified health service, and many speakers supported the call for further health education of the public. Edinburgh promotes this spirit of public instruction by placarding her tramway stations with electrically-lighted health notices—"The M.O.H. says 'Spitting causes Disease,'" and the like, while Dr. C. S. Thomson (M.O.H. Deptford) told how his authority had asked him to give lectures on their policies and procedures, which he had found well attended. Expression was often given in the meetings of the Institute to the new outlook of preventive medicine, which aims to-day less at the direct reduction of mortality, and more at the reduction of disabling disease and at securing increased health and exalted resistance for the individual. Future advances, it is becoming felt, will depend largely on individual citizens by whom patient attention must be given to the laws of health.

The next Congress of the Institute will mark the jubilee of the Institute, which was founded in 1876; the meeting will be held in London on July 5th to 10th, 1926, under the presidency of the Duke of Northumberland, the opening meeting taking place in the Guildhall and the sectional meetings at Westminster.

ANIMAL PATHOLOGY AND PHYSIOLOGY.

ORGANISED research into animal diseases has been sleepy in its progress, but there are signs of an awakening movement. During the past year the Ministry of Agriculture's laboratory, the Institute of Animal Pathology at Cambridge, and the Animal Diseases Research Association at Glasgow, have all been actively engaged in the elucidation of puzzling factors in creature maladies. Braxy in sheep has always exacted a heavy toll in some districts and a vaccine is now being employed successfully against it. In 62,000 sheep which were inoculated, the death-rate was only one-quarter of that in untreated sheep. Lamb dysentery is another well-established disease, and persists so obstinately on some farms that the rearing of lambs has had to be given up. Mr. S. H. Gaiger, F.R.C.V.S., considers that the organisms which produce it are all "soil bacteria" and that the disease does not occur in the uterus of the ewe before lambing. This theory has been tested during the 1925 season, and the statistics of the Wellcome Physiological Research Laboratories, Beckenham, seem to indicate that inoculation of pregnant ewes with antigens made from the organisms isolated from cases of the disease has produced a decrease in the lamb fatalities. Scrapie and trembling or louping ill, two distinct diseases of sheep, have also been investigated; but not much progress has been made with them, as both seem to be of obscure nervous origin and transmitted by tainted stock. Grass disease in horses and mammitis in cows and ewes have also received attention, and as time goes on much of the leeway in the domain of research in animal diseases will be gradually overhauled. The Institute of Animal Pathology has carried out a considerable number of routine examinations for veterinary surgeons during the year and is getting together a good library on animal diseases. Mr. W. A. Pool, M.R.C.V.S., late of the Indian Veterinary Service, has joined the research staff as senior research assistant. On the physiological side work has been no less interesting. The Rowett Research Institute, which was established as far back as 1912, near Aberdeen, for the study of animal nutrition, has issued a series of collected papers under the editorship of Dr. J. B. Orr, the director.[1] They cover a great variety of subjects, including the mineral metabolism of pigs and its relation to rickets; the respiratory exchange of goats; the water balance of the body; the nature of scrapie in sheep; the diet appropriate to the intensive raising of chickens; and many other topics of interest and importance. To anyone who likes browsing in a various collection of printed matter—and what genuine student does not?—the volume will make a strong appeal. It will remind him of the great difficulty of trying to keep track of any subject in the flood of present publications. For example, it is of obvious moment that those interested in respiration should consult the papers on the influence of external temperature, work, and pregnancy on the energy exchange of the goat. These, however, have not been published also in one of the physiological magazines, but only in the *Journal of Agricultural Science*, and we have to thank Dr. Orr for the dissemination of the information. We wish him and his colleagues all success in their second volume. Their work has a wider interest than the nutrition of farm animals.

THE NEW MILK AND DAIRIES REGULATIONS.

THE suspended Milk and Dairies (Consolidation) Act, 1915, will come into operation on Sept. 1st next. This Act repeals and re-enacts a number of provisions contained in the Contagious Diseases (Animals) Acts and the Sale of Food and Drugs Acts with regard to milk and dairies. It also reproduces a number of amendments and new provisions which were contained in the Milk and Dairies Act, 1914, the operation of which was deferred. Sections 1 and 2 extend the list of purposes for which Orders may be made under the Contagious Diseases (Animals) Act, 1878, and it is proposed as soon as possible to make an Order under the new powers. Sections 3, 4, and 5 contain provisions similar in effect to those contained in a number of local Acts for stopping the supply of milk likely to cause tuberculosis. Under the new Act the duty of enforcement is placed on the council of the county or county borough in which the cows are kept, and any Order made by them will prohibit the sale of the affected milk in any area. Section 4 requires the medical officer of health of the county or county borough to make the necessary investigations on receipt of a notice from any other medical officer of health. The Tuberculosis Order of 1925 providing for the slaughter of bovine animals affected with certain specified forms of tuberculosis and for the payment of compensation in respect of animals so slaughtered will come into operation on the same day as the Act, and it will be the duty of the local authority discovering the presence in a herd of a tuberculous animal to cause it to be slaughtered or to report the matter to the relevant authority for the appropriate action. Sections 6 and 7 re-enact provisions contained in the *Sale of Food and Drugs Act*, 1899. Section 8, in conjunction with Section 14, enlarges the power of the local authority to take samples of milk at any time before the milk is delivered to the consumer. An authorised officer of one authority may by notice require the officer of another authority to take samples of milk within his area under the Sale of Food and Drugs Acts, when the sample will be deemed to have been taken within the area of the officer giving the notice. Section 9 amends the provisions of the Sale of Food and Drugs Acts with regard to the warranty defence. Where such a defence is pleaded by a purveyor of milk a sample from a corresponding milking must be taken in the course of transit or delivery to the purveyor, and if the owner of the cows so requests, a further sample must be taken at the dairy at which the cows are kept. The warranty defence will not be available where the sample in respect of which the proceedings are taken is a mixture of milk obtained from more than one seller or consignor. Power is also given to the local authority of the district in which the first sample was taken to take proceedings against the seller or consignor. For the purposes of the new Act the expression "dairy" does not include a shop from which milk is not supplied otherwise than in the properly closed and unopened receptacles in which it was delivered to the shop. The information is set out at length in Circular 612 of the Ministry of Health, which may be obtained from H.M. Stationery Office for 1*d*.

GIOVANNI BATTISTA GRASSI.

Italy has lost one of her most eminent sons by the death of Prof. Grassi in Rome last May. Born at Rovellasca, province of Como, in 1854, he graduated at Pavia in 1878 and occupied the chair of Comparative Anatomy at Catania until 1895, when he was called to the same position in the University of Rome, where he remained till his death. Pre-eminently a biologist, he was at the same time physician and naturalist. His own view was that the physician would do well to be something more of a naturalist and that the naturalist should not lose sight of the man in his researches and analogies. Grassi's conception of the importance of the intimate connexions which existed between man and the rest of the animal world, connexions which consisted in identity or analogy of function, and in the adaptation of their life in common, led him to the outposts of a new science of which he was one of the founders and to which he gave the name of parasitology. The relations which the lower animals had with man, the specific adaptation in alternate hosts and parasitic cycles, the analogies between parasitic diseases in animals and man, revealed to him their great importance in pathology. Of this trend of study, which subsequently assumed immense and grandiose proportions and on which is founded the greater part of tropical medicine, he was a pioneer. In the preface to his work on Parasitology, which appeared in 1881, he wrote:

> "I remember, when still a student and attending the course of general pathology, being often seized with an intense curiosity to know why the study of disease in every kind of animal was not included, and when I saw the pathologist endeavouring to reproduce experimentally human diseases in frogs and rabbits, I wondered why these and all other animals were not studied when they became diseased naturally. Even a limited application of Darwinism to pathology, would suffice to illuminate us with a new and fruitful light."

Thus Grassi guessed at the future which was reserved for bacteriology; indeed, it might be maintained that circumstances alone prevented him becoming an Italian Koch. His scientific energies were directed into many and various fields of research and are a matter of surprise and admiration for all who are acquainted with his work. While still a student he discovered the ova of *Ankylostoma* in the fæces, he investigated the developmental cycle of *Strongyloides stercoralis*, and demonstrated that the dog's flea was the intermediate host of *Dipylidium caninum*, that *Hymenolepis nana* had no intermediate host, while that of *Gigantorhyncus* was a beetle of the genus *Blaps*. From his researches on the *Helminths* were derived the fundamental conceptions which later on led him to the study of malaria and sand-fly fever. On these followed investigations on phylloxera, on the metamorphosis of the murenoids, and the constitution and development of the society of *Termites*, for which he was awarded the Darwin medal of the Royal Society of London, a series of researches any one of which would have secured his name to posterity. Working with Bignani and Bastianelli in 1898 on three species of mosquitoes, he finally concentrated his suspicions on *Anopheles claviger*, to the exclusion of *Culex* and other blood-sucking diptera, and in 1900 published his "Studies of a Zoologist on Malaria," in which Grassi placed on an impregnable foundation the doctrine that malaria cannot exist without *Anopheles*, the truth of which the universal experience of the last 25 years has confirmed. Eight years later the University of Leipzig conferred on him the honorary degree of doctor. To zoologists Grassi's name is very familiar because of his well-known work in association with Calandruccio, which first shed light upon the life-history of the common eel.

Grassi was a man of complex personality owing to certain qualities and even defects of character. Within a small and delicate frame, a wonderful example of the domination of mind over matter, he preserved a nervous and forceful will and a formidable capacity for work. In his laboratory from 7 A.M. till noon and from 1 to 8 P.M., with two or three hours' sleep and at work again before daybreak, such, even at an advanced age, was his constant habit, interrupted frequently by peregrinations into every part of Italy, often in his early days going on foot with his parcel of food in his pocket. He had derived a systematic precision from the schools of Gegenbaur and Bütschli at Heidelberg, and his marriage was a permanent link with Germany, but his genius remained essentially Italian. A man of large and clear ideas, not simply a specialist, but a focus of several specialties, he possessed the rare facility of changing quickly a mental attitude, of taking up a new point of view, of knowing how to free himself from the tyranny of an idea or an a priori conception. Even his prose had a marked personal style; he was not an elegant writer, but amid laboured and involved pages there were to be found terse phrases and sparkling epithets. He was full of strange contrasts, jealous of scientific fame, yet modest withal, and under a rough exterior concealing a simple good nature. He was an idealist in science; his ardour and even passion for work; his exactitude towards himself and others; his courage in exposing himself to dangerous experiments; his renunciation of everything except investigation and study, were fed by this sacred flame. His last wish expressed his philosophy of life: to be buried without public honours in a quiet cemetery in the Roman Campagna among the simple folk who were victims of malaria. This thought is emphasised in an admirable biographical notice by Dr. Massimo Sella,[1] which ends with the valediction: "Italians who are not forgetful will visit Thee in that lonely spot when they desire to strengthen their faith and their will, oh thou Great Italian."

Sir Charles Sherrington, P.R.S., Waynflete Professor of Physiology in the University of Oxford, has been appointed a member of the Medical Research Council from Sept. 30th next, in the vacancy caused by the retirement of Dr. Henry Head under the provisions governing the rotation of membership.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXV.—THE TREATMENT OF FLATULENCE

I.*—GASTRIC FLATULENCE.

FLATULENCE is a term applied to a collection of gas in the stomach or intestines in sufficient quantity to give rise to a sensation of fullness or even pain which is relieved when the gas is expelled. It may conveniently be considered according to its localisation in *the stomach or intestines, its genesis being* essentially different in the two situations.

Few symptoms are complained of *so commonly as gastric flatulence*, and certainly few are so misunderstood, a state of affairs due in large part to the persistence in medical parlance and literature of that mischievous term, flatulent dyspepsia. It will be well to emphasise at the outset that flatulence with very few exceptions is a symptom resulting from the habit of aerophagy or air swallowing, and that the fermentation theory, apart from rare instances, *is a* legacy of obsolete conceptions and has little more than historical interest to recommend it. Aerophagy *is the cause; flatulence and eructations are its* manifestations. A common courtesy amongst Mohammedan races, a gross breach of good manners in Western countries, a frequent associate of all forms of indigestion, and a visceral tic in an individual of neuropathic tendency, the results *of aerophagy* appear in so many and varied connexions that to maintain the term, flatulent dyspepsia, as a sufficient diagnosis is but to conceal the cause under the cloak of a prominent symptom. Under normal conditions the fundus of the stomach contains a variable quantity of air which is swallowed with the food and the saliva. This fundic air-bubble, so striking a feature of X ray examination, may be increased by: (*a*) deficient absorption of air; (*b*) fermentation or putrefaction of the gastric contents; (*c*) aerophagy or air swallowing.

Deficient Absorption of Air.

Deficient absorption *of air from* the stomach and intestines is a very rare cause of flatulence, but does occur at times as a result of chronic venous stasis in cirrhosis of the liver and cardiac failure. Treatment consists in the measures usually adopted for the relief of an embarrassed circulation, in the careful regulation of the diet, and in the exhibition of drugs to relieve the discomfort. It should be borne in mind that digitalis may not be well tolerated in cases of heart failure with prominent gastric symptoms and may, indeed, aggravate them. As regards the diet the general principles are: (1) that meals should be small and dry and not more than three in the day; (2) that the intervals between meals should be not less than five hours and that the principal meal should be taken in the middle of the day; (3) that fats and carbohydrates, with the exception of glucose, should be used sparingly. For the immediate relief of distension small doses of the carminative oils are undoubtedly useful, and as shown by Plant[1] act by increasing tone and contractile power. Saundby recommended the following combination:—

℞ Tinct. zingib. fort.
Olei cinnamomi .. .. .. 10 ♏
Olei carui .. .. 1 ♏
Olei cajuputi .. .. .. 1 ♏
.. .. .. 1 ♏

Dose 2—5 drops.

Oil of turpentine, 10–15 drops on a lump of sugar or in a capsule, is also of value, *and a teaspoonful of* powdered charcoal after meals is another well-tried remedy.

It should not be forgotten that to the flatulence of cardiac failure may be added the discomforts of aerophagy.

Fermentation and Putrefaction.

It is perhaps excusable for the layman to think that his food "may turn to wind in his stomach" and thus generate an apparently inexhaustible *supply of gas, but such a view* can no longer receive the serious attention of the medical profession nor be allowed further to obscure important issues. The rate of gastric emptying renders it impossible for flatulence to result from fermentation in the stomach *apart from structural narrowing* of the pylorus, and even in this condition flatulence is a somewhat rare complaint. The symptom may occur both in benign and cancerous stenosis and the eructated gases may be sour-smelling, putrid, or have the odour of sulphuretted hydrogen. Organic disease *should be* suspected whenever the eructations are malodorous, though, exceptionally, an odour may be imparted by oral or naso-pharyngeal sepsis. Investigation will speedily show the nature of the case and indicate the treatment proper to the condition, but as a temporary measure of relief and a useful preliminary to surgical procedure, frequent gastric lavage with hot water should be undertaken together with the oral administration of charcoal.

Aerophagy.

Aerophagy or air swallowing is, par excellence, the *cause of flatulence. In moderation* a feature of normal digestion aerophagy with consequent flatulence becomes abnormal under four main conditions.

1. As an unpleasant habit amongst those who bolt their food, or for other reasons are unable to masticate it *sufficiently*.

2. As a sequel to excessive salivation or sialorrhœa. This may result from oral or naso-pharyngeal irritation. Ryle[2] produced aerophagy in himself by painting the pharynx with an iodine preparation. Dental caries, *pyorrhœa, neglected dentures*, tonsillitis, nasopharyngeal catarrh, and more rarely œsophageal cancer are well-recognised causes.

3. As a symptom in those whose main complaint is indigestion. Flatulence may accompany any type of *dyspepsia, whatever* its cause, and irrespective of any abnormal conditions of gastric motility and secretion. The mechanism of aerophagy in these cases is described by Hurst[3] as follows: "The patient feels some slight discomfort in the stomach, which he thinks is due to 'wind' and which he hopes he will be able to 'disperse' by eructation; as there is *really no excess of gas present*, the attempt proves unsuccessful and results in the swallowing of air. After half a dozen attempts have been made, air being swallowed on each occasion, the stomach becomes so distended that an attempt is at last successful." As Bennett[4] points out, the habit is acquired so *gradually and unthinkingly that the patient is usually* unaware of it until it has been brought to his notice. Although flatulence may occur with dyspepsia from any cause, its association with gall-bladder disease is often so striking as to have some diagnostic value.

In this connexion it may be noted that Bennett[4] has recently drawn attention to the extremely important rôle played by aerophagy as a cause of post-operative acute gastric dilatation.

4. As a psychoneurosis. In patients of neuropathic tendency, as a result of fear, anxiety, or other morbid obsession, aerophagy may occur as a habit and should

be regarded, according to Hurst, as a visceral tic, but it is probable that here, too, the aerophagy had its origin in some gastric discomfort long forgotten. This type of patient presents a familiar appearance; his face is a mirror of his mental and abdominal unrest; he lives on the atmosphere, and his resounding gusty eructations are a source of grave perplexity to himself and mingled astonishment and dismay to his friends and neighbours. In such a one the air does not enter the stomach but is drawn into the œsophagus and immediately and violently expelled. Excessive salivation may be a contributory factor, whilst cardiac symptoms such as palpitations, tachycardia, arrhythmia, and pseudo-angina may occur and make his distress the more acute.

Treatment of Flatulence Due to Aerophagy.

The aims in treatment will be three: (1) To search for and if possible remove the cause. (2) To treat the aerophagy. (3) To treat the flatulence resulting from it.

1. In all cases where the main complaint is of indigestion a careful investigation, by the usual methods, of the upper alimentary tract is essential, for as Bennett[4] says, an organic cause must not remain concealed by such camouflage as flatulent dyspepsia. In a word, the investigation of these cases is that of a dyspeptic and the treatment will vary according to its results.

2. When the symptom is so obtrusive as to demand treatment apart from its underlying cause, it becomes necessary to treat the aerophagy itself. When possible an emphatic assurance as to the absence of gross disease should precede a careful explanation of the mechanism of air swallowing supported, if need be, by a personal demonstration. The patient must be told to suppress all desire to eructate, since no one ever has or ever will be able to bring up wind voluntarily, and any efforts in this direction will but result in the swallowing of air. In the majority of cases explanation on these lines is readily accepted and is usually all that is requisite to break the habit, but in obstinate cases the patient may be advised to hold some small object, such as a cork or cigarette-holder, between the teeth after meals or he may wear a tight band or collar around the neck to act as a constant reminder of his habit. Meals should, in the main, be dry, since less air is swallowed with solid than liquid food, and should be eaten slowly. Excessive salivation when of purely nervous origin should be treated with belladonna, and the bromides may be added for their general sedative effect. In hysterical patients the passage of a large-sized stomach-tube and its maintenance in position for half an hour may be tried, the patient being informed that this procedure will cure the condition. In cases of exceptional severity where the flatulence is no more than a prominent manifestation of a generalised psychoneurosis complete isolation combined with psychotherapy is desirable.

3. The drug treatment of gastric flatulence is of quite secondary importance, but for the immediate relief of discomfort the carminatives are valuable and in view of Plant's work their use is rational. They have already been referred to.

T. L. HARDY, M.D. Camb., M.R.C.P. Lond.,
Assistant Physician, General Hospital,
Birmingham.

EXTENSION OF HAMPSHIRE COUNTY HOSPITAL.—A comprehensive scheme for the improvement and extension of this hopsital, the first instalment of which will cost £55,000, has been set on foot by a county meeting at Winchester. The nurses' home is to be extended at a cost of £26,000; an isolation block and a new out-patients' department are also to be provided. At present 21 nurses are housed in a worn-out army hut; another 27 live in houses outside the hospital, with the consequence that last winter many of them suffered from colds and sore throats. The hospital was founded as long ago as 1736.

SOME GENERAL REFLECTIONS ON PUBLIC HEALTH ADMINISTRATION.

BY J. H. L. CUMPSTON, M.D. MELB., D.P.H. LOND.,
DIRECTOR-GENERAL OF HEALTH, COMMONWEALTH OF AUSTRALIA.

IV.—THE PROPOSED FAR-EAST CONVENTION.[*]

THE draft Convention, submitted by Dr. Norman White to the League of Nations as a considered proposal for the regulation of Port Health Organisation and procedure in the Far East, challenges serious examination, because Dr. White has appreciated the difficulties known to exist by all engaged in quarantine activities, and he has dared greatly in departing from the beaten path in his endeavour to find a remedy.

In Australia the conditions in the past have been such, and our present problems are so nearly related to those with which the report deals that we can feel well-disposed to Dr. White's attempts even if we cannot accept his draft Convention. We have been sorry that he could not visit Australia, as we feel we would have benefited from his vigorous outlook, and perhaps our 50 years of evolution in matters of quarantine might have provided precedents of legislative form of some assistance to him in his work. While Australia may not be generally recognised as a country in the Far East, it is only five days steam from Batavia to Darwin, and three days from Banjoewangi to Broome. Also there is continuous traffic down the coast, so that steamers from infected Asiatic countries travel from one Australian port to another within and beyond the incubation period of each of the diseases dated from the infected Asiatic port. Moreover, as Australia is entirely free (except during epidemic invasions) of these diseases, the epidemiology—i.e., the maritime epidemiology—of these diseases can be studied under conditions exceptionally free from complicating factors.

It is therefore perhaps justifiable to apply our experience in an attempt to discuss this draft Convention in the light of the forthcoming official revision of the International Sanitary Convention.

A. *The Draft Regarded as a Convention.*

Dr. White would probably be the first to admit that his draft requires some re-casting before it could be adopted as a legal document. The various points which seem to call for comment are as follows:—

(*a*) Certain expressions of loose form require reconsideration as to form alone, omitting for the moment any discussion of their significance:—Para. 11: "Measures shall be taken at the port of departure . . . in so far as these are practicable. Para. 18 provides that an inspection is to be made by a health officer immediately prior to the vessel's departure and this examination shall ensure that the vessel is mechanically clean in all parts prior to storing cargo or receiving passengers, and no communication with the shore shall be permitted after the completion of this examination. The paragraph says this, although it does not mean this.

(*b*) A Convention is a binding legal agreement by which every signatory country undertakes to adopt the procedure therein prescribed. The essential nature of a Convention excludes the concept of an ulterior power exercising jurisdiction or compulsion over the individual signatories. Despite this basic principle, the Convention contains internal evidence of the presumption of such a power. Para. 4 provides that ports shall be classified into three categories according as they possess or do not possess "qualified and adequate health staff," "adequate apparatus for fumigation," "suitable quarantine station," and other things "safe" or "adequate." The draft Convention leaves mysteriously undetermined the identity of the authority who shall determine the "adequacy" and so "classify the ports." But the preamble definitely states that "it would be advisable to leave the classification of ports to a central international epidemiological bureau."

Putting aside all questions of the authority controlling this bureau, and the acceptability to various countries of such external determination of fundamental data on which quarantine operations are based, it is essential for a Convention that the nature of the classifying authority and the scope of its functions be specified in the body of the Convention. Para. 16.: It is provided that the measures which shall be taken with regard to small-pox shall follow the procedure in Article 36 (of the proposed modification of the International Sanitary Convention) except that all the measures "shall be compulsory and not optional." The proposed modification provides that "it is recommended that the following measures shall be adopted." Dr. White's suggestion would, if adopted, involve for each country an obligation to carry out the prescribed measures under compulsion, presumably by some authority having power to compel. Dr. White probably means that each country should agree that the measures proposed should be enforced. This criticism is not over-meticulous, as Dr. White submits his text as a legal instrument fully prepared for insertion in the text of the Convention. The phraseology of para. 16 (*d*) would probably require some revision before it could be incorporated (if accepted in principle) in the text of a Convention.

---

[*] Parts I., II., and III. appeared in THE LANCET of July 11th and 25th, and August 1st respectively.

B. *Basic Principles of the Draft Convention.*

The principal considerations which seem to have inspired Dr. White are stated in his preamble to the draft Convention. These are:—

(1) The importance of the human being in relation to plague-transmission is exaggerated in the International Sanitary Convention.

(2) The sanitary state of the port of departure should not be ignored to the extent permissible under the *International* Sanitary Convention.

(3) The action to be taken on arrival of vessels should be based on the sanitary state of the port of departure rather than on the condition of the vessel, and there is no necessity to classify ships as infected, suspected, and healthy, as is done in the International Sanitary Convention.

It is likely that Dr. White will find considerable agreement with these principles, even amongst those concerned with the drafting and revision of the Paris Convention of 1912. Probably the best way to discuss the practical application of these principles is to begin by considering a vessel newly arrived in port in a country free from the diseases in question. But before doing so, it may be permissible to point out that in all of the discussions of maritime quarantine the lessons of maritime epidemiology have been almost ignored and the *facts* of terrestrial epidemiology have been assumed to apply. All experience shows that maritime epidemiology *has* principles and laws of its own, and these laws should be studied much more completely than they have been hitherto.

A vessel on arrival at a clean port presents a problem for immediate solution. There are two elements in the problem: (*a*) Whence does this vessel come; (*b*) what has been, and is, her sanitary condition. Dr. White divides ships into infected or non-infected. An infected ship is one on which a case of one of the diseases in question is present or has occurred during the current voyage. (A curious omission is the lack of specific reference to rodent plague unaccompanied by a "case" of human plague, cf. paras. 16 (*a*) 1 and 3.) A non-infected ship is one which is not or has not been infected in the above sense.

Infected and Non-infected Ships.

Dr. White does not use these terms "infected" and "non-infected,". but they are necessary for discussion.

(I.) *The Infected Ship.*—The measures proposed by Dr. White for dealing with the infected *ship* do not differ essentially from those in the proposed revision of the Paris Convention, except that the "suspected ship" disappears and all vessels which have been *infected* during the voyage are regarded as infected. As a theoretical principle this commends itself as *quite sound*; but on examination the Paris Convention provisions commend themselves as equally sound and the distinction between "*infected*" and "suspected" is a matter of convenient classification. If Dr. White had to deal with a vessel arriving at a port with cases of plague on board he would: (*a*) inspect all on board; (*b*) disembark and isolate the sick and pay special attention to all who had been in contact with the sick; (*c*) disinfect bedding and quarters; (*d*) deratise the ship.

If, on the other hand, the vessel has no case on board and has had no fresh human case for seven days, he could not isolate the sick and he would, on his *own* showing, not consider it necessary to isolate contacts, but all the other things he would do. This procedure is precisely what the Paris Convention prescribes. The same is true of cholera and yellow fever.

There is, therefore, no force to the proposal that the class of "suspected" ship should disappear. It is artificial, certainly, but it is a convenient way of detailing the difference in measures applied to: (1) a ship which arrives in port with fresh cases, and (2) the ship which has had only an isolated initial case during the voyage. As a practical matter the difference is that between the vessel which has embarked a passenger or member of the crew incubating plague or cholera and the vessel which apparently has a source of infection on board or a spreading infection from the initial case.

(II.) *The Non-infected Ship.*—Dr. White first proposes (para. 15) that "cognisance" shall be taken of: (*a*) ships from infected or suspected ports; (*b*) infected ships from clean ports; (*c*) ships from clean ports carrying plague-suspicious or cholera-suspicious cargo from infected localities.

From the point of view of daily routine administration this proposal is incomplete. It assumes that Governments will *take no cognisance of other vessels.* Let us take an actual case. A vessel left San Francisco, which at that time was neither "infected" nor "suspected" with small-pox. It carried some passengers from the interior of the United States incubating small-pox. The vessel called at Honolulu, Suva, Auckland, and arrived at Sydney. The surgeon did not report small-pox. If the Government of Australia had taken no cognisance of that ship the cases of small-pox would never have been known, having been missed at the other ports. It is therefore necessary that a special distorted significance be given to the word "cognisance," or else that some other formula be devised permitting of the routine medical inspection of all oversea vessels arriving. The Paris Convention assumes this, and the Quarantine Act of Australia specifically provides for it and covers all of Dr. White's groups. In the Australian Act all oversea vessels (and in the event of an internal epidemic all vessels from the infected area) are "subject to quarantine"; all "infected" vessels (in Dr. White's sense) are "ordered into quarantine" *and then dealt with* according to the "suspected" and "infected" procedures of the Paris Convention; and all clean ships from "proclaimed" ports (which are Dr. White's infected and suspected ports) and their cargo or water-tanks are dealt with in accordance with the recognised procedure in each case.

Vessels on Arrival.

Dr. White's introduction leads the reader of his report to expect that he will introduce into his proposed procedure for dealing with vessels on arrival at any port some reduction of completeness depending upon the action taken at a first or second class port of departure. But the only reference to this is found in the preamble: "leaving the port health officer to determine the facilities and immunities that would be accorded vessels that had been treated adequately before departure from ports of the first or second class." Further, there is *para.* 18, in which it is proposed that a health officer shall inspect all vessels leaving an infected port of the first or second class. Quite apart from the anomalous position that a health officer will not know in any week until the next Saturday night whether his port is infected or not, it is interesting to examine the significance of this classification. The difference between ports of the first and the second classes is the possession by the former of fumigation apparatus and a quarantine station. It is not clear what effect the possession of a quarantine station, with a capacity of 500 passengers and crew, at a port is to have on the risk to overseas countries in view of the present obligation under the Paris Convention on the competent authority to prevent the embarkation of all persons liable to *transmit infection.*

The pre-occupation of each *Government* is the protection of its own people from imported disease. A Government in Europe or Australia is concerned only that a vessel approaching its shores shall have left an infected country in a clean *condition.* This is already covered by Article 12 of the Paris Convention and its achievement is fully possible without a quarantine station; for this purpose, and, in fact, for all the purposes of Dr. White's draft Convention, a port might well be classed as first class without a quarantine station, provided the port of disembarkation were so equipped. Here lies, possibly, the true purpose of Dr. White's proposal—viz., that some form of inducement is necessary to encourage all important ports in the Far East to provide themselves with a quarantine station and other essential equipment. Nobody with any experience will do other than applaud this purpose, but it is brought into the Convention in an illogical and resultless manner. Actually, so far as one can read the report, the design is that the "central epidemiological bureau" shall be in a position to encourage by moral pressure the establishment of such stations. That is a larger issue with many implications direct and indirect. It is sufficient to say here that such a design cannot be introduced in a subtle and indirect way, but must, if adopted, find clear and definite expression in legal form in the text of the Convention.

Vessels on Departure.

A very important practical provision, which might with advantage be incorporated in the International Sanitary Convention, is found, but in very tentative form, in para. 21 of Dr. White's draft Convention. This article reads as follows :—

> "With regard to other communicable diseases not coming within the scope of articles in this Section, each signatory Government shall endeavour to apply to departing vessels such measures as may be requested by the Government of the country of the port of destination."

To a certain extent this practice is recognised in the Australian Quarantine Act and Regulations, at least to the extent that exemption from deratisation measures is permitted if these have been effectively carried out according to prescribed means at an overseas port of departure. The same provision has been utilised in connexion with cholera, if the water-supply at an overseas port has been from a reliable source. In Dr. White's report, however, the position is left unsatisfactory in that the same basis of action is dealt with partly by Article 18, which provides for inspection by a medical officer at the port of departure, and Article 16 in which the reduced measures of protection at the port of arrival are based upon action of the kind now contemplated at the port of departure.

The Dutch Government has submitted to the Health Committee of the League of Nations a similar suggestion. In Holland the Government is authorised to exempt vessels going from one port from any health formalities before entering another port provided all necessary measures of disinfection, deratisation, &c., had been taken at the first port; the Dutch Government think that, from an international point of view, it would be highly desirable to extend the scope of this measure in the interests of commerce. This proposal was the subject of some discussion, and it was decided to entrust to a Commission the task of studying the practical measures necessary to facilitate the conclusion of agreements between Governments, aiming at the establishment of this procedure on a standard of scientific basis. It would probably be found that there is uniform agreement as to this principle of bringing into operation the protective measures against the transmission of disease at the point where the risk actually exists. It is merely the expression in another administrative field of the military principle that the best defence line is the enemy's frontier.

When bubonic plague occurred in Brisbane and Sydney, 1922–23, the immunity of the other portions of the Commonwealth from plague was due entirely to the fact that such measures were taken as to ensure the departure from the infected areas in an entirely rat-free condition of every single article of merchandise.

Progress Necessarily Slow.

Undoubtedly international sanitary measures will be improved from their present basis in proportion as measures of sanitary precaution can be taken in regard to traffic at the time of departure from the infected country, and each modification of the Sanitary Convention aiming at securing this result, step by step, would be hailed as an improvement. The prospects which we now have of securing the inclusion of a logically considered scheme of action in this regard in the next revision of the text of the Sanitary Convention represent one of the greatest advances which has been made during the evolution of the sanitary conventions. It is felt, however, that tangible results in this direction will be slow to materialise, as each port, in order to secure recognition, will need first to provide proper equipment, and second, to establish the confidence of other countries that the equipment is reliable.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 226.)

THE COUNCIL OF BRITISH OPHTHALMOLOGISTS.

(App. LXIII. and Q. 17772–17934.)

EVIDENCE on behalf of this Council was submitted by the following medical men: Mr. E. Treacher Collins, Mr. J. Herbert Fisher, and Mr. S. Mayou.

The Council is strongly of opinion that the examination of the eyes should be carried out by qualified medical practitioners, and supported its view by drawing attention to the report of the Departmental Committee on the Causes and Prevention of Blindness, in which the importance of the provision of adequate facilities for ophthalmic treatment is emphasised, and a definite recommendation made that "all persons with defective vision should first consult a competent medical practitioner."

A subcommittee of the Council jointly with the British Medical Association have made recommendations which include the following :—

1. That the so-called optical benefit should be designated ophthalmic benefit. Ophthalmic benefit would include examination and prescription for spectacles, if required, and such operative treatment and advice as can be given at a single consultation at the consulting room. A report, when necessary, would be given for the guidance of the private practitioner.
2. That insured members of every Approved Society should in any case of ocular disorder or visual defect apply to their insurance practitioner.
3. If the insurance practitioner considered the case one requiring special advice or treatment he would give the applicant a certificate, enabling him to consult a specialist at a reduced fee.
4. A list of ophthalmic medical practitioners qualified and willing to see members of Approved Societies at a consultation fee of £1 1s. should be prepared.

The Council considers that no course of training short of that required for full medical qualification can produce the skill and judgment necessary for the examination and treatment of the eyes. It is well known that changes in the refraction of the eye are often produced in the early stages of serious eye disease. In many such cases an optician may be successful in raising the acuteness of the vision to a normal standard, but he would almost inevitably fail to recognise the disease which is the cause of the refractive error. In fact, disease very serious to the eye, or threatening even life, may occur in an eye with perfect acuity of central vision.

Without the use of drugs to dilate the pupil or paralyse the focusing muscle, in many cases the optician cannot measure accurately the error of refraction, or be in a position to identify the cases which demand medical advice and treatment. If he were allowed to use such drugs he would become an even greater danger to the community by reason of serious disease which he in his ignorance might produce. The ophthalmic surgeon must have an adequate knowledge of diseases of the brain and central nervous system, of the blood-vessels and vascular system, of the kidneys, of the nose and its accessory sinuses, of the various ductless glands, &c. In fact, there is no branch of medicine which is not in close relationship with this special domain, nor is there any specialty in which a general medical knowledge is of greater importance.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

On the question of the competence of the general practitioner to make an effective examination and diagnosis Mr. Fisher said:—

(Q. 17770.) Our idea was, I think, that the panel practitioner would be a cog in the wheel of administration of ophthalmic benefits, probably not actually doing himself any large proportion of the ophthalmic benefit, but here and there, there might be a panel practitioner who might have sufficient special knowledge to deal, at any rate, with some branches of ophthalmic cases. That would not be very frequent.

This led later to the following question:—

(Q. 17801.) Does it not simply resolve itself into this, that in a very large proportion of cases the general medical practitioner would be bound to say, and quite honestly bound to say: "This is beyond me altogether; go to an ophthalmic surgeon"; and that would involve a fee of a guinea in every case?—In a large majority of cases, certainly.

As to there being a sufficient supply of specially trained practitioners for a service for the whole insured population, the witnesses stated that a list had been drawn up jointly with the British Medical Association, and there was a sufficient supply for present needs and no doubt that the number would rapidly increase.

The witnesses agreed that the training of the general practitioner in eye work was quite inadequate, and the Council has repeatedly made representations on the subject to the General Medical Council. The Council was in possession of evidence of the danger of a patient going straight to the optician, the mistakes including overlooked disease, patients unnecessarily alarmed about their condition, and unnecessary glasses frequently supplied.

With regard to clinics, the witnesses said that if any clinic system were to be established it would have to be independent of the present eye hospitals, where it would be physically impossible to get through the cases in the accommodation available, but, in fact, the Council were opposed to clinics generally and regarded them as impracticable for the treatment of the insured population.

THE OPHTHALMIC BENEFIT COMMITTEE.

(App. LXIV. and Q. 17035–18020.)

This evidence was given by the following medical men: Mr. H. L. Eason, Mr. G. H. Pooley, and Dr. Charles F. Harford.

The Ophthalmic Benefit Committee represents the interests of ophthalmic medical practitioners who are willing to take part in an Ophthalmic Medical Service. The Committee is in hearty agreement with the evidence submitted by the Council of British Ophthalmologists and the British Medical Association. The Ophthalmic Benefit Committee came into existence about a year ago. Its membership is approximately 280, excluding the North of England, which has its own society, represented on the Committee by Mr. Pooley.

The witnesses confirmed the evidence given above as to the dangers arising from going direct to the optician, and said that the cases which they could produce in evidence involved both trained and unqualified opticians.

(Q. 17053.) Will you give us briefly some indication of the nature of the cases?—The common disease is glaucoma which, as you know, is one of the serious diseases which may affect the eye. Early cataract is another. Disease of the retina associated with some general medical disease such as renal disease and Bright's disease, which are apparent to any skilled observer and are only local indications of general disease.

They objected strongly to some of the advertisements of opticians, by which they considered that the public were misled. The optician might examine the inside of the eye through a lens, but without medical training he could not appreciate the importance of what he saw.

(Q. 17072.) By looking at the inside of the eye you have the opportunity of seeing a portion of the human body during life under a high magnified power. Arterial disease, nervous disease, many other diseases, can be seen in the eye before being recognised elsewhere.

Interesting evidence was given with regard to cases of hæmorrhage in the retina productive of headache and yet easily overlooked in a mere testing for glasses. It was suggested by a member of the Commission that this appeared to prove too much and to lead to the conclusion that people should go to the ophthalmic surgeon at intervals. The witnesses agreed that these cases would not necessarily be discovered by providing that persons should go for correction of error of vision to an ophthalmic surgeon rather than to an optician. Mr. Harford explained the matter as follows:—

(Q. 17080.) People are being persuaded by these specious advertisements that if they have a headache, if there is discomfort in various ways, they should not go to their doctor, but to an optician. If they had gone to their doctor he would have been able to throw more light on the other symptoms. People seldom have hæmorrhage of the retina without some other symptom, and, therefore, all things have to be discovered, and the right person to do this is the patient's own medical practitioner who is dissatisfied with their state of health, and feels that they ought to have further advice, which would mean an examination by an ophthalmic surgeon.

With regard to clinics, the grave defect was felt to be that it was a contract system whereby so many persons had to be seen in an afternoon whether the cases were important or not; the Committee thought that specialists would never be persuaded to take up clinic treatment under the Insurance Acts, though in reply to later questions bearing on the possibility of an improved and better organised system of clinics, Mr. Eason said:—

(Q. 18020.) In addressing ourselves to the fundamental question, the question of clinic or no clinic is to us of secondary importance compared to the main point, which is giving to the insured person when he goes to the clinic or anywhere else the best possible attention. If the first point is accepted then we can work out the machinery.

CHEMISTS' EVIDENCE.

(App. LXV and Q. 18030–18205.)

Mr. A. R. Melhuish and Mr. G. A. Mallinson gave evidence on behalf of the Retail Pharmacists' Union, which was founded to carry on, in addition to other activities, certain work, formerly undertaken by the Pharmaceutical Society of Great Britain, which, as the result of a test case in the High Court, was deemed to be outside the Society's charter. The membership of the Union is limited to those carrying on retail businesses as chemists, and it represents the whole of the panel chemists of the country through the Pharmaceutical Committees, all of which acknowledge the Union as the representative body. Scotland has its own separate organisation and the evidence related to conditions in England and Wales.

Under the National Health Insurance Acts prescribing is separated from dispensing excepting in many rural areas where the doctor necessarily does both. The chemist has no control over the supply, it being his business to meet the requirements of the doctor's prescriptions.

The arrangements under the National Health Insurance Act for the supply of medicines through the chemists are, it was stated, as complete as any which exist in private practice, and are a vast improvement on the conditions previously existing under the "club" practice system. The insured person can now have exactly the same medicines as the most wealthy patient can purchase. He has the right to the same range and quality of drugs and medicines. The doctor is the deciding factor, and whatever he orders the patient will get from the panel chemist.

The arrangements work well and there is a supply of chemists adequate to maintain a service for the dependants of insured persons. It was suggested that the separation of prescribing from dispensing is a natural result of the developments in medical science. The doctor has now no time to spare to make himself a specialist in pharmacy and dispensing. An advantage upon which too much stress cannot be laid is that the doctor may prescribe during his rounds and the patient can get the medicine without waiting for the doctor to return home, because the chemist gives a continuous all-day service. Further, the fact that a patient can be dismissed immediately his prescription has been written lessens the congestion in doctors' waiting-rooms. The hospital practice of using stock mixtures is not viewed favourably by chemists, who maintain that the tendency should be in the other direction, towards the higher-class medical practice of writing individual prescriptions.

With regard to delays that may occasionally arise in making up prescriptions, it was thought that there might be closer coöperation between Panel and Pharmaceutical Committees in regard to surgery hours and the hours of closing chemists' shops.

As to the checking of medicines supplied by chemists, the witnesses said that the machinery of the Food and Drugs Act had not proved fair or effective. The chemists were themselves desirous of adequate tests being made and of proper disciplinary action, and the Retail Pharmacists' Union had submitted a scheme to the Ministry of Health. In general the scheme provides for medicines being made up by the chemists on prescriptions specially written by the doctors and presented by an agent of the Insurance Committee, who proceeds to divide the medicine in the presence of the chemist and takes one-half away to be analysed. The doctor does not write these special prescriptions because he is under contract to do so, but because it assists in promoting the efficiency of the service. For what they described as manipulative error, the witnesses thought that an all round 5 per cent. margin should be allowed.

On the subject of advice asked for by customers, the following questions were answered :—

(Q. 18205–8.) You mentioned that people come to you for general advice. I suppose about a cut finger and things of that sort ?—Yes. And you advise them ?—Yes. In a certain sense you act as medical advisers in a small way ? Hardly that. You act as a layman with a knowledge of medicine ?—It is what you would do in your own family.

It was claimed in the course of examination that as between chemist and client there was something of the same desirable personal relationship which counts for so much as between doctor and patient and that in any case it was clear that a person thought much more of medicine supplied by the chemist than he did of supplies from a dispensary or the out-patient department of a hospital.

DRUG STORE PROPRIETORS.

(App. LXVI. and Q. 18266–18436.)

This evidence, given by Mr. W. Huntrods and Mr. A. Hutchison, contains statements of a rather sweeping character suggesting unnecessary services rendered by doctors to insured persons and fraudulent practices on the part of chemists, such as the alteration of prescriptions for their pecuniary benefit, and the supplying of short measures and inferior articles—statements which the witnesses had not the material necessary to support in oral examination.

Other statements were as follows: Persons earning more than £100 per annum should not be compelled to be insured because they are generally of a higher education and social standing than the average working man. . . . The administration of medical benefit should be simplified by establishing State medical officers and dispensaries. . . . There is not the slightest doubt that the National Health Insurance Act has created a neurotic drug-loving nation. . . . Careful consideration should be given to (1) repeal of the Act; (2) the taking of a plebiscite; (3) making the Act voluntary.

BRITISH PHARMACEUTICAL CONFERENCE.

GLASGOW, JULY 27TH–31ST.

THE sixty-second annual meeting of the British Pharmaceutical Conference was held at Glasgow during the last week in July. Mr. Edmund White, B.Sc., F.I.C., the chairman, in his address, dealt with recent and coming events in British Pharmacy.

Chairman's Address.

Mr. White began by referring to the progress that has been made with the scheme for establishing a laboratory for the biological examination and standardisation of therapeutic substances; rooms in the Pharmaceutical Society's buildings had been allocated for the laboratories, and with the passing into law of the Therapeutic Substances Bill, the Society will be able to meet the demand for an institution which will be competent to examine and issue certificates for therapeutic substances requiring standardisation by biological and physiological methods. There is no doubt that such standards will receive extended recognition as and when facilities are provided for their establishment and they are shown to be reliable indications of value and potency. Mr. White next referred to the recent remarkable growth in the membership of the Pharmaceutical Society and then to the prominent part the Society is now taking in international pharmacy, and the steps lately taken towards the advancement of pharmaceutical education and research at home. In this latter connexion he mentioned the establishment this year of the degree of Bachelor of Pharmacy, instituted by London University under conditions which will enable the Society to accept it as a registrable qualification, and the raising of the standard of the curriculum and examination for the qualification of pharmaceutical chemists. The fact that London University has recognised pharmacy as a branch of learning necessitating the provision for facilities for the highest form of education and research will do much to place pharmacy in its proper relation to the other sciences. Finally, Mr. White, after referring to the difficulties in the way of the international unification of pharmaceutical methods, said he believed that a serious effort to unify pharmacy in the English-speaking communities would yield encouraging results at once: "You have only to compare the British Pharmaceutical Codex with the United States Pharmacopœia to see how British and American practice runs on similar lines, and the time has now arrived when our great overseas Dominions, such as Canada, Australia, New Zealand, and South Africa, should be invited to take a more active share in moulding the destinies of pharmaceutical practice as reflected in our Imperial and National Pharmacopœias."

Scientific Papers.

In the Science Section 19 papers were contributed, some of them being of a high standard and bearing evidence of patient work. In a paper on the Identification of Alkaloids, W. M. Cumming, D.Sc., F.I.C., and D. Brown, B.Sc., described how, using potassium ferro-cyanide as a reagent, the alkaloidal salts in definite crystalline form may be obtained from neutral, acid, and alcoholic solutions. The paper was copiously illustrated by lantern-slides, showing the characteristic appearances of the crystallised salts. H. Finnemore, B.Sc., F.I.C., read a paper on West Australian Sandalwood Oil, in which he suggested that this oil may prove to be as efficacious medicinally as the East Indian oil. There seems to be little, if any, reason why the B.P. specification for sandalwood oil should not be made to include the West Australian product. A. J. Jones gave the results of his investigation of the question of the variability of the density of bismuth carbonate; incidentally he remarked that it was a mistake to suppose that a light carbonate always suspended or diffused better than a heavy one. A typical pharmaceutical paper was contributed by F. J. Dyer and R. Melville on Phosphorus Pill; the official formula produces a pill that is too soft for general practice, and the authors, while presenting a new formula, suggested that the administration of free phosphorus in pill form should be replaced by some other method, as, for instance, phosphorated oil in capsules. A communication from the Pharmaceutical Research Laboratory of the Pharmaceutical Society was made by T. E. Wallis, B.Sc., F.I.C., and Ellinor J. Mowat, on true and false santonicas; from time to time there appear on the market specimens of santonica which closely resemble the genuine drug in external appearance, but which contain no santonin. The examination of a large number of species of *Artemisia* belonging to the section *Seriphidium* enabled the authors to select those features which are useful in distinguishing between nearly related species and to formulate characters by which the flower heads of genuine santonica of commerce can be identified with certainty. Another communication from the same laboratory was made by G. R. A. Short on the structure of coccinium; these two papers illustrated the valuable research work which is being done in the Pharmaceutical Society's laboratories. A paper of more direct interest to practising pharmacists was contributed by G. T. Elsdon, B.Sc., F.I.C., on the testing of insurance dispensing; he made observation on 800 mixtures, dispensed under the Insurance Act, which he had examined and showed that in recent years adulteration was almost entirely absent; incidentally, he mentioned that it was now possible to obtain machine-made bottles having an accuracy of about 2 per cent., in all cases. Bernard F. Howard, F.I.C., and Oliver Chick drew attention to two minor discrepancies in the quinine monographs of the British Pharmaceutical Codex; their comments will be of assistance to the Revision Committee. In a paper on the estimation of small amounts of reducing sugars in urine F. Wokes, B.Sc., drew attention to the importance of carrying out accurate estimations of small amounts of reducing sugar in urine and suggested a micro-method for use by pharmacists; he also showed how to make allowance for variations in urine due to diet and the time of collection of samples.

Among other papers contributed were the following: A Chemical Examination of the Oleo-Resin of Indian Valerian Root, by K. Bullock, M.Sc.; the Identification by Chemical Methods of Drugs Containing Tannins, by A. H. Ware; Cochineal: the Utility of Assay Methods in the Estimation of Comparative Colour Values, by A. O. Bentley and S. Meakin; Note on Morphine Hydrate, by D. B. Dott; the Picrates of the Opium Alkaloids, by C. W. Maplethorpe and N. Evers, B.Sc., F.I.C.; the Colorimetric Estimation of Benzoic Acid in Cordials, by A. J. Jones; A Note on the Official Process for Assaying Galenicals of Hydrastis, by H. B. Mackie and H. A. Cleary, B.Sc.; A Note on Oleated Mercury, by F. J. Dyer and K. M. Metcalfe; the Vitamin Content of *Cortex Limonis* B.P., by S. G. Willimott, Ph.D., B.Sc., and F. Wokes, B.Sc.

At a meeting of delegates from the Pharmaceutical Society's branches, held in connexion with the Conference, under the chairmanship of Mr. P. F. Rowsell, President of the Society, a paper was read by Mr. F. Pilkington Sargeant entitled An Historical Survey of the Charters and Acts of Parliament Governing the Society's Activities leading up to the Present-day Position. Mr. J. Keall read a paper on the Dangerous Drugs Act. A meeting of the newly-formed League of Ex-Service Pharmacists was also held under the chairmanship of Major E. S. Peek. Papers were contributed on the Development of Pharmaceutical Service in the Army, by Captain Hill, and on the Use of Antiseptics in War, by Mr. F. Wokes.

CANADA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Montreal Vital Statistics: A New Milk By-law.

Dr. Boucher, Director of the Health Department of Montreal, has issued recently the annual report of his department for 1924, in which the vital statistics of Montreal are discussed. These show that there has been, compared with 1923, a decrease in the death-rate (14·87 as against 15·67), an increase in the birth-rate (32·75 as against 31·91), and a slight falling off in the number of marriages per 1000 (9·24 as against 9·49). The figures are calculated on the basis of a population estimated at 655,800. The average of the surplus of births over deaths for the past ten years was 9·749, showing consequently an increase of 1000 over the average of the past ten years. Under the head of infant mortality the report states that 3151 deaths of children under one year were registered in 1924, as against 3057 in 1923, or an increase of 91. The infant mortality death-rate for 1924 is the lowest observed in Montreal since the organisation of the bureau of statistics, but Dr. Boucher finds a decrease of 2·4 per 1000 births not sufficient, and believes it would be improved by reliable milk by-laws.

A by-law has been drawn up by Dr. Boucher, and was prepared to the end that a more effective hygienic control over the condition of milk might be imposed by employing educative measures towards the producer and retailer. The by-law embodies the rules for producing a clean, healthy milk, and keeping, transporting, and handling it until it reaches the consumer. In those cities, according to Dr. Boucher, where pasteurisation has been adopted, it has resulted in the appreciable diminution of deaths among nurslings. New York is quoted, where the ravages of tuberculosis have decreased amongst children under 15 years through pasteurisation by 53 per cent., when the figures for 1924 are compared with those 25 years ago. The new by-law allows the sale of natural and sterilised, as well as pasteurised, milk, so that the public may buy what they desire. Pasteurisation seems to be in high favour in the cities both of Canada and the United States, but the new milk by-law, which it was anticipated would pass without objection, has been held up temporarily, and at the time of writing has not been passed.

Inadequate Accommodation in the Hospitals of Montreal.

Superintendents of the Montreal institutions for treating the sick and injured, English and French, find the overcrowded condition of their institutions serious. Major A. K. Haywood, superintendent of the Montreal General Hospital, pointed out recently that Montreal requires 1600 more beds for general cases. In his opinion, a city with adequate hospital facilities should have 5 to 7 beds per 1000 inhabitants, whereas Montreal has only 3 to 5. But he considers the reason that Montreal cannot build additional wards is not so much because of the capital expenditure as because of the cost of maintaining the beds when accommodation has been found. Every public ward, he went on to say, means a loss to the hospital. With the present large deficits facing the boards of management, these cannot consider the addition of more beds until assurance is given as to the financing of them. Dr. L. A. Lessard, secretary of the Notre Dame Hospital, has stated that every day his hospital is compelled to turn away emergency cases. The situation is better now than it was and than it will be in the winter, but is serious even at this season.

A Proposed Jewish Hospital in Montreal.

Dr. N Vincent, President of the Montreal Clinical Society, at a meeting of the organising committee of a proposed Jewish and General Hospital in Montreal, stated that there is accommodation for only 1 out of 10 cases which require hospital treatment. He pointed out that there were English Protestant hospitals, French Catholic hospitals, and he hoped that there would be a Jewish hospital, where the particular tenets of the Jewish religion as to diet could receive due consideration. Jewish graduates would also have a better opportunity of learning clinical work, though the proposed hospital would not be entirely for Jews, of whom there are between 60,000 and 70,000 in Montreal. Dr. A. Bercovitch, secretary of the organising committee, announced that the medical men interested in the project had promised $20,000 towards its cost. The erection of the hospital as proposed would cost about $500,000, and accommodate 150 beds. A resolution was passed unanimously voicing the need of the institution.

Fellowships at McGill University.

Awards of four Cooper Research Fellowships in experimental medicine at McGill University have been announced recently. The Cooper Research Fellows are: Dr. A. R. Elvidge, who held a Fellowship last year and is reappointed for another year; Dr. G. Garvin Miller, now of the Ford Hospital, Detroit; Dr. G. S. Mills, Montreal General Hospital; and Dr. J. C. Clelland, of the Royal Victoria Hospital, Montreal, who are appointed to Fellowships for the first time. The Cooper Research Fellowships take their name from the late James Cooper, of Montreal, who died in 1912, leaving in his will a fund of $50,000 to promote research and to improve teaching.

Treatment of Insane in Canada.

A radical change in the methods of treatment of the insane, or the presumably insane, is to be introduced into the Province of Quebec. It is the establishment of a psychiatric hospital, in which the classification of the mentally disordered or abnormal will be facilitated. In such an observation hospital cases will be studied in order to decide what kind of treatment is required in cases which are considered curable. Of course the incurables will be transferred to the usual insane institutions. In Great Britain this mode of treatment is in use to some extent, and in the United States is employed more widely. The psychiatric hospital in the Province of Quebec, the construction of which is in progress, will provide accommodation for 250 patients.

Motor-car Accidents in the Province of Quebec.

In 1924, in the Province of Quebec, motor-car accidents were responsible for 139 deaths. The total number of deaths for 1923 was 117. Thus 1924 shows an increase of 19 per cent. over 1923. It is believed that to the carelessness of motor-car drivers the majority of accidents were due, especially to contempt of traffic rules.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Influence of Factory Work on Parturition.

Dr. Hirsch, of Berlin, has conducted a valuable piece of research concerning the effects of factory work on pregnancy, birth, and the post-partum period. Most of his investigations were carried out on women workers in textile factories, of whom there are in Germany more than 500,000. On an average 40 per cent. are married, and among these the total annual number of pregnancies is about 10,000. It is interesting to learn that the ratio of miscarriages occurring in women working at spinning machines and at looms, compared to the incidence among women not engaged in factory work, is as 16 to 1 and 6 to 1 respectively, whilst the number of still-births in the textile districts is double the average for the whole country. Only 30 per cent. of the births among female textile factory workers were normal. This is due, Dr. Hirsch holds, to the fact that narrowness of the pelvis is very frequent among textile workers, because women begin factory work at a time when the body is still growing. The incidence percentage of narrow pelves and of pathological births increases in direct ratio to the youth of the worker. Female textile workers are worn out at the age of 40, when the male worker is still in possession of his strength. The Berlin Medical Society, before which Dr. Hirsch read a paper on the subject, resolved to direct a petition to Parliament to the effect that women should not be allowed to work more than six hours per day in the third and fourth month of pregnancy and four hours in the fifth and sixth month, and should not work at all during the last three months; that seats should be provided for pregnant women whose work requires long periods of standing or walking, and extra rooms where they might repose in cases of necessity; that the institution of canteens which already exist in many of the larger factories should be made compulsory; that medical women should be appointed as factory inspectors for the especial care of pregnant women; that troubles connected with pregnancy should be regarded as illnesses under the Workmen's Insurance Act; that sick-clubs therefore should be compelled to provide in cases of pregnancy and normal confinements medical attendance, and sick-pay similar to the provisions made in the case of an illness.

Amendment of the Workmen's Insurance Acts.

By a recent Act the law concerning the insurance of workmen against accidents has been amended to the effect that certain trade diseases now rank as accidents. By the terms of the Act a medical man attending a workman who is suffering from a disease due to his trade is obliged to notify the case to the local insurance office (*Versicherungs-Amt*) which has to inquire into the matter and to provide for the indemnification of the workman according to the provisions of the accidents insurance law. The following diseases are to come under the provisions of the Act: poisoning by lead, phosphorus, mercury, arsenic and their compounds, benzol and its congeners; further, chimney-sweeps' cancer, tar cancer, paraffin cancer, pitch cancer, cancer caused by anthracite and similar substances; glass makers' cataract, diseases caused by Rontgen rays, ankylostomiasis in miners, and pulmonary diseases of metal miners in Saxony.

Lectures on Puberty.

A series of lectures on puberty were delivered before the Berlin Pædiatric Society recently. Prof. Spranger first dealt with the subject from the psychological standpoint; he pointed out that other circumstances besides the sexual symptoms characterised puberty; such general symptoms were the beginning of consciousness of the ego, the awakening of phantasy, leading often to poetical production. The fluctuations between predilections of quite different kinds—e.g., music and sports—were common. He differentiated sexuality from eroticism. Early sexual enlightenment, he held, was advisable when it answered questions which are in the foreground of adolescent interest, but it was altogether doubtful whether enlightenment was able to give control of the sexual impulse. Young people desire to be understood, and he who understands a youth may easily influence him, whilst youths are antipathic to people who do not understand them. Dr. Aron spoke on puberty as a physiological process, and expressed his conclusion that puberty depended on the glands of internal secretion which contribute to the growth of the body. The hormones of the generative glands were active in the last stage of the condition. He drew attention to the fact that in townsfolk puberty developed earlier than in country people, and earlier in the well-to-do class than in the proletariat. The more slowly puberty developed, he said, the more natural it was. The principal cause of early puberty in town people was due, in his opinion, to the fact that they had less physical exercise than country people. Muscular activity, which is a greater factor in the life of country children, stimulated growth and strengthened the heart and the lungs. A future generation would be able to state whether the spread of sports among the town youths had had an influence on the age of onset of puberty, and had rendered the development of town people more like that of country people.

Death of Prof. Bernard Naunyn.

Prof. Bernard Naunyn, one of the most celebrated German physicians and teachers of clinical medicine, died recently in Baden-Baden at the advanced age of 86. He was born in Berlin, his father being at one time mayor of that city. He studied medicine in Bonn and in Berlin, where he graduated in 1862. He first made researches in anatomy, but soon became an assistant to the late Prof. Frederichs, who was at that time one of the most distinguished clinicians of the University of Berlin. Naunyn's work on jaundice and on the theory of fever led to his appointment as professor of medicine at the University of Dorpat. In 1871 he held a similar appointment at Berne, and in the following year at Königsberg. In 1888 he succeeded Prof. Kussmaul at the University of Strassburg, and he remained there until 1904. On retiring from active work he lived in Baden-Baden, and gave his services as consultant when necessity demanded to the international public of that health resort. During the war, in spite of his advanced age, he acted as consulting physician to a military hospital at Baden. His numerous published works concerned localisation of cerebral diseases, dealing particularly with aphasia and cerebral pressure, also diseases of the gall-bladder and diabetes. Together with Prof. Klebs and Prof. Schmiedeberg he founded in 1873 the *Archiv für Experimentelle Pathologie und Pharmakologie*, and with the late professor of surgery, Dr. Mikulicz, the *Mitteilungen aus den Grenzgebieten zwischen Medicin und Chirurgie*. He also published three essays on general medical questions, and latterly wrote his memoirs. Among his well-known assistants were Profs. Minkowski, Eichhorst, and Weintraud. He was an excellent teacher, and was much esteemed by his patients and his pupils.

An Epidemic of Enteric Fever.

In Anklam, Pomerania, a town of 15,000 inhabitants, a severe epidemic of enteric fever has broken out. The number of cases at present is 200, of which eight have proved fatal. The patients have been conveyed partly to the university hospital of Griefswald, which is in the neighbourhood, and partly to the local infirmary where a number of provisional barracks have been erected; 3000 of the inhabitants have undergone preventive inoculation. It has been possible to prevent the spread of the disease to the neighbourhood, a very important fact, as Anklam is situated near the favourite Baltic seaside resorts, which are at present crowded with people from Berlin and other cities. The Government Health Department have sent Prof. Lanz to the spot where, in conjunction with the professor of clinical medicine and the director of the Hygienic Institute of Greifswald University, he has examined the cause of the epidemic. They have ascertained that the epidemic started from a dairy near the town, where the majority of the patients had bought their milk.

CHELSEA HOSPITAL FOR WOMEN.—This hospital has opened a floor with 18 beds for the accommodation of patients able to pay a weekly fee of £5 5s. Very moderate fees will be charged for operations. The diseases admissible, as in the rest of the hospital, are those peculiar to women. The success obtained by the hospital in this work is shown by the available figures. H.M. The Queen, the Patron, in paying recently a visit to the new nurses' home in connexion with the institution, expressed her gratification at the extension of the activities of the hospital, whose benefits are now being brought within the reach of a class of patient for whom there is at present insufficient accommodation.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the health statistics for 1924 of a group of districts situated on the fringe of the metropolis:—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Willesden U.D. ..	171,161	16·6	10·4	1·04	1·2	2·2	32	73	1·4
Tottenham U.D.	153,100	18·6	10·2	0·90	1·1	2·0	32	62	2·4
Ilford U.D. ..	88,701	16·2	9·9	0·73	1·3	1·0	10	43	0·7

Willesden.

Dr. George F. Buchan reports that ten cases of small-pox occurred in Willesden in 1924, all in one house. The type varied from mild small-pox to the most virulent hæmorrhagic form, and three of the ten cases proved fatal. The infector of the first of the ten cases could not be traced. Supervision of the contacts proved effective and there was no spread of the disease in Willesden. Two of the contacts under observation developed small-pox, one in the Midlands and one in London, and were at once isolated on the appearance of symptoms without further spread of the disease. Out of 12 notified cases of puerperal fever, nine of the births were attended by a doctor, one took place before the arrival of the doctor, one occurred in a London hospital, and the twelfth was attended by a midwife. Twenty-nine cases of ophthalmia neonatorum were notified. In 19 the birth was attended by a doctor, in nine by a midwife, and the remaining case was born in a hospital. Vision was unimpaired in 25 cases; in one case the eye was permanently injured and in two cases the babies died from other causes, and one case was under treatment at the end of the year. The percentage of babies brought to the welfare centre was 17·9, and the number of births to expectant mothers who attended the ante-natal clinic was 255. The total births were 2843. Thus less than 10 per cent. of the mothers attended the antenatal clinic. The schools for mothers have made good progress and the mothers have shown a marked interest in the lectures and demonstrations arranged. Among the school-children nearly 90 per cent. of the medical defects followed up were treated, but only 11 per cent. of the dental defects. In an appendix on school dental work, Dr. Buchan points out "that as a result of all the dental inspection, clerical notices, and visitation by the health visitors only 563 out of 9358, or 6 per cent., of the children requiring treatment received the same up to Dec. 31st, 1923." Dr. Buchan goes on to urge the importance of attention to the teeth during childhood.

Dr. Buchan gives the history of the negotiations for an open-air school which have been going on since July, 1911, and points out that the provision of an up-to-date open-air school with a mentally defective stated that there is accommodation for only 1 out of 10 cases which require hospital treatment. He pointed out that there were English Protestant hospitals, French Catholic hospitals, and he hoped that there would be a Jewish hospital, where the particular tenets of the Jewish religion as to diet could receive due consideration. Jewish graduates would also have a better opportunity of learning clinical work, though the proposed hospital would not be entirely for Jews, of whom there are between 60,000 and 70,000 in Montreal. Dr. A. Bercovitch, secretary of the organising committee, announced that the medical men interested in the project had promised $20,000 towards its cost. The erection of the hospital as proposed would cost about $500,000, and accommodate 150 beds. A resolution was passed unanimously voicing the need of the institution.

Fellowships at McGill University.

Awards of four Cooper Research Fellowships in experimental medicine at McGill University have been announced recently. The Cooper Research Fellows are: Dr. A. R. Elvidge, who held a Fellowship last year and is reappointed for another year; Dr. G. Garvin Miller, now of the Ford Hospital, Detroit; Dr. G. S. Mills, Montreal General Hospital; and Dr. J. C. Clelland, of the Royal Victoria Hospital, Montreal, who are appointed to Fellowships for the first time. The Cooper Research Fellowships take their name from the late James Cooper, of Montreal, who died in 1912, leaving in his will a fund of $50,000 to promote research and to improve teaching.

Treatment of Insane in Canada.

A radical change in the methods of treatment of the insane, or the presumably insane, is to be introduced into the Province of Quebec. It is the establishment of a psychiatric hospital, in which the classification of the mentally disordered or abnormal will be facilitated. In such an observation hospital cases will be studied in order to decide what kind of treatment is required in cases which are considered curable. Of course the incurables will be transferred to the usual insane institutions. In Great Britain this mode of treatment is in use to some extent, and in the United States is employed more widely. By the terms of the Act a medical man attending a workman who is suffering from a disease due to his trade is obliged to notify the case to the local insurance office (*Versicherungs-Amt*) which has to inquire into the matter and to provide for the indemnification of the workman according to the provisions of the accidents insurance law. The following diseases are to come under the provisions of the Act: poisoning by lead, phosphorus, mercury, arsenic and their compounds, benzol and its *congeners*; further, chimney-sweeps' cancer, tar cancer, paraffin cancer, pitch cancer, cancer caused by anthracite and similar substances; glass makers' cataract, diseases caused by Rontgen rays, ankylostomiasis in miners, and pulmonary diseases of metal miners in Saxony.

Lectures on Puberty.

A series of lectures on puberty were delivered before the Berlin Pædiatric Society recently. Prof. Spranger first dealt with the subject from the psychological standpoint; he pointed out that other circumstances besides the sexual symptoms characterised puberty; such general symptoms were the beginning of consciousness of the ego, the awakening of phantasy, leading often to poetical production. The fluctuations between predilections of quite different kinds—e.g., music and sports—were common. He differentiated sexuality from eroticism. Early sexual enlightenment, he held, was advisable when it answered questions which are in the foreground of adolescent interest, but it was altogether doubtful whether enlightenment was able to give control of the sexual impulse. Young people desire to be understood, and he who understands a youth may easily influence him, whilst youths are antipathic to people who do not understand them. Dr. Aron spoke on puberty as a physiological process, and expressed his conclusion that puberty depended on the glands of internal secretion which contribute to the growth of the body. The hormones of the generative glands were active in the last stage of the condition. He drew attention to the fact that in townsfolk puberty developed earlier than in country people, and earlier in the well-to-do class than in the proletariat. The more slowly puberty developed, he said, the more natural it was. The principal cause of early puberty in town people was due, in his opinion, to the fact that they had less physical exercise than country people. Muscular activity, which is a greater factor in the life of country children, stimulated growth and strengthened the heart and the lungs. A future generation would be able to state whether the spread of sports among the town youths had had an influence on the age of onset of puberty, and had rendered the development of town people more like that of country people.

Death of Prof. Bernard Naunyn.

Prof. Bernard Naunyn, one of the most celebrated German physicians and teachers of clinical medicine, died recently in Baden-Baden at the advanced age of 86. He was born in Berlin, his father being at one time mayor of that city. He studied medicine in Bonn and in Berlin, where he graduated in 1862. He first made researches in anatomy, but soon became an assistant to the late Prof. Frederichs, who was at that time one of the most distinguished clinicians of the University of Berlin. Naunyn's work on jaundice and on the theory of fever led to his appointment as professor of medicine at the University of Dorpat. In 1871 he held a similar appointment at Berne, and in the following year at Königsberg. In 1888 he succeeded Prof. Kussmaul at the University of Strassburg, and he remained there until 1904. On retiring from active work he lived in Baden-Baden, and gave his services as consultant when necessity demanded to the international public of that health resort. During the war, in spite of his advanced age, he acted as consulting physician to a military hospital at Baden. His numerous published works concerned localisation of cerebral diseases, dealing particularly with aphasia and cerebral pressure, also diseases of the gall-bladder and diabetes. Together with Prof. Klebs and Prof. Schmiedeberg he founded in 1873 the *Archiv für Experimentelle Pathologie und Pharmakologie*, and with the late professor of surgery, Dr. Mikulicz, the *Mitteilungen aus den Grenzgebieten zwischen Medicin und Chirurgie*. He also published three essays on general medical questions, and latterly wrote his memoirs. Among his well-known assistants were Profs. Minkowski, Eichhorst, and Weintraud. He was an excellent teacher, and was much esteemed by his patients and his pupils.

An Epidemic of Enteric Fever.

In Anklam, Pomerania, a town of 15,000 inhabitants, a severe epidemic of enteric fever has broken out. The number of cases at present is 200, of which eight have proved fatal. The patients have been conveyed partly to the university hospital of Griefswald, which is in the neighbourhood, and partly to the local infirmary where a number of provisional barracks have been erected; 3000 of the inhabitants have undergone preventive inoculation. It has been possible to prevent the spread of the disease to the neighbourhood, a very important fact, as Anklam is situated near the favourite Baltic seaside resorts, which are at present crowded with people from Berlin and other cities. The Government Health Department have sent Prof. Lenz to the spot where, in conjunction with the professor of clinical medicine and the director of the Hygienic Institute of Greifswald University, he has examined the cause of the epidemic. They have ascertained that the epidemic started from a dairy near the town, where the majority of the patients had bought their milk.

CHELSEA HOSPITAL FOR WOMEN.—This hospital has opened a floor with 18 beds for the accommodation of patients able to pay a weekly fee of £3 5s. Very moderate fees will be charged for operations. The diseases admissible, as in the rest of the hospital, are those peculiar to women. The success obtained by the hospital in this work is shown by the available figures. H.M. The Queen, the Patron, in paying recently a visit to the new nurses' home in connexion with the institution, expressed her gratification at the extension of the activities of the hospital, whose benefits are now being brought within the reach of a class of patient for whom there is at present insufficient accommodation.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the health statistics for 1924 of a group of districts situated on the fringe of the metropolis:—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Willesden U.D. ..	171,101	16·6	10·4	1·01	1·2	2·2	32	73	1·4
Tottenham U.D.	163,100	18·6	10·2	0·99	1·1	2·0	32	62	2·4
Ilford U.D. ..	88,791	16·2	9·9	0·73	1·3	1·0	19	43	0·7
Edmonton U.D.	70,450	19·7	10·1	1·05	1·1	2·2	—	56	5·1
Wimbledon B...	58,090	14·0	11·1	0·76	1·5	2·2	37	72	3·7
Hendon U.D. ..	57,530	16·2	9·2	0·71	1·4	1·4	22	43	2·1
Finchley U.D...	47,810	15·0	9·2	0·73	1·0	1·8	29	50	3·0

U.D. = Urban district. B. = Borough. — = Information not included in report.

Willesden.

Dr. George F. Buchan reports that ten cases of small-pox occurred in Willesden in 1924, all in one house. The type varied from mild small-pox to the most virulent hæmorrhagic form, and three of the ten cases proved fatal. The infector of the first of the ten cases could not be traced. Supervision of the contacts proved effective and there was no spread of the disease in Willesden. Two of the contacts under observation developed small-pox, one in the Midlands and one in London, and were at once isolated on the appearance of symptoms without further spread of the disease. Out of 12 notified cases of puerperal fever, nine of the births were attended by a doctor, one took place before the arrival of the doctor, one occurred in a London hospital, and the twelfth was attended by a midwife. Twenty-nine cases of ophthalmia neonatorum were notified. In 19 the birth was attended by a doctor, in nine by a midwife, and the remaining case was born in a hospital. Vision was unimpaired in 25 cases; in one case the eye was permanently injured and in two cases the babies died from other causes, and one case was under treatment at the end of the year. The percentage of babies brought to the welfare centre was 17·0, and the number of births to expectant mothers who attended the antenatal clinic was 255. The total births were 2848. Thus less than 10 per cent. of the mothers attended the antenatal clinic. The schools for mothers have made good progress and the mothers have shown a marked interest in the lectures and demonstrations arranged. Among the school-children nearly 90 per cent. of the medical defects followed up were treated, but only 11 per cent. of the dental defects. In an appendix on school dental work, Dr. Buchan points out "that as a result of all the dental inspection, clerical notices, and visitation by the health visitors only 563 out of 9358, or 6 per cent., of the children requiring treatment received the same up to Dec. 31st, 1923." Dr. Buchan goes on to urge the importance of attention to the teeth during childhood.

Dr. Buchan gives the history of the negotiations for an open-air school which have been going on since July, 1911, and points out that the provision of an up-to-date open-air school with a mentally defective department would enable the unsuitable and inefficient schools at Furness-road, Leopold-road, and Leinster-road to be abolished. The percentage of verminous children has been reduced from 20 in 1914 to 7·1 in 1924. In December the Education Committee approved the formation of an experimental class for stammerers. Willesden is badly off for an efficient home-nursing service. There are some eight nurses at work in connexion with churches and associations, in addition to the one home nurse employed by the council, whereas Dr. Buchan estimates that some 30 to 40 are needed. An orthopædic clinic for crippled children is another urgent need, and it is suggested that a local clinic be established to be based on the Stanmore Hospital and staffed by that institution. The staff of sanitary inspectors for dealing with housing inspection Dr. Buchan considers to be quite inadequate, and he suggests it be augmented.

Tottenham.

Dr. David C. Kirkhope reports that "the one great outstanding environmental defect in the district is the lack of housing accommodation." Quite a number of houses are ripe for demolition. The housing of Tottenham people has not been improved by the erection of L.C.C. houses, as these are let to families displaced from other parts of London. The pollution of the tributaries of the Lee has received special consideration, but the condition of the river is not yet satisfactory. Dr. Kirkhope hopes that this river "may yet come to be regarded as a place of beauty and a source of pleasure." A preliminary account is given of the trial of an anti-scarlatinal serum, and Dr. Kirkhope thinks the results are encouraging. The last effort to establish a branch of the District Nursing Association in Tottenham failed, and Dr. Kirkhope suggests that the council should "not allow this matter to rest until Tottenham is adequately equipped with a nursing staff for the domiciliary treatment of those requiring expert nursing care in illnesses other than those of an infectious character." The school report shows that 137 cases of otorrhœa have been treated by ionic medication and that in 82 of these the discharge from the ears has ceased. It is not claimed that these 82 have been cured and they will be kept under observation for a long period. Arrangements have been made with the North Middlesex Hospital for the operative treatment of children suffering from enlarged tonsils and adenoids, and provision is made for retention of cases in hospital where necessary.

Ilford.

Dr. A. H. G. Burton says that the housing difficulty in Ilford "has been very little eased." An inquiry at the end of the year showed "that just over 150 gallons of Grade A milk (or about one-tenth of the total sale of all milk) was retailed daily in the district." Dr. Burton thinks that the standard of Grade A milk is not exceptionally high and does not see why all milk sold should not be Grade A. He thinks the designations of milk have been unnecessarily multiplied. He finds little demand at present for pasteurised milk sold as such. "Much milk is pasteurised and sometimes re-pasteurised, but is sold as pure fresh milk to the consumer." Dr. Burton gives some comparisons with past years in order to indicate the efficiency of the school medical service. In 1908 there were 135 cases of ringworm in the Ilford schools; at the end of 1924 there were only five. The 1919 percentage of uncleanliness—namely, 10·7—became 4 in 1924. After the war there were 30 cases of itch discovered by medical inspection and 110 at the clinic. Last year the corresponding figures were two and three respectively. The cases of impetigo, or contagious sores, have been reduced from 546 to 243. An open-air school is still under consideration, but a site has been approved by the Board of Education. There is no school for mentally defective children. There are 30 young persons over 16 who were certified to be feeble-minded when at school in Ilford and who received no training. "There are 20 feeble-minded children at present attending the elementary schools and seven not attending any school who should be receiving education in a special school, either day or residential."

Edmonton.

Dr. H. W. Harding records that ten cases of encephalitis lethargica were notified in Edmonton, three of which ended fatally. Of the seven survivors, one shows a lack of concentration only; another, who was previously dull, falls to sleep at frequent intervals for a short time; a third tells unreasonable lies and has become cowardly; a fourth is mentally normal, but almost completely paralysed and has to be fed; a fifth suffers from twitching of the lids and double vision; a sixth suffers from double vision, is sleepy during the day, and easily tired; the seventh has left the district. Dr. Harding knows of two other cases which were not diagnosed or notified. Both are of the Parkinsonian type with "a mask face, general weakness, and mental lethargy." A big scheme, to cost £140,000, is in hand to improve the sewage farm which it is hoped will prevent flooding in the low-lying parts of the town and enable the sewers to be self-cleansing. The sanitary inspector reports continuous trouble from gypsies of the lowest class. Trenches have been dug across entrances in order to prevent their access to vacant land. The corporation are negotiating for the purchase of a recreation ground which is a favourite encamping place of the gypsies and which it is hoped to "control" when the property has been transferred.

Wimbledon.

Dr. A. Gilmour reports that 87 working-class dwellings of the parlour type are in course of erection on the housing estate. A new system of water filtration has been installed at the municipal public bath, Latimer-road. Negotiations are still proceeding with the Ministry of Health for a sanction to a site and buildings for a new day-nursery. Ten cases of encephalitis lethargica were notified, eight during the first six months of the year. Two cases were admitted to the isolation hospital, one of which was of the myoclonic type and ended fatally. The other cases were of a mild type, resembling influenza, and followed by giddiness, double vision, and drowsiness. A close investigation of the history did not establish any direct contact with other cases. A piece of vacant land, at the junction of Wandle-, Leyton-, and Denburgh-roads, caused a nuisance owing to the dumping of offensive matter. All endeavours to trace the ownership failed, and the council obtained an Order from the Ministry of Health under Section 21 of the Public Health Amendment Act of 1907 to clean and fence the land. This was done after copies of the Order and statutory notices had been fixed to a post erected on the land for the requisite period. The school dental scheme needs extension, as the staff is unable to attend to the "leavers," which means that much of the good done by previous work is wasted.

Hendon.

Dr. T. S. McIntosh reports that the scheme for the new permanent isolation hospital, delayed by the war, now only awaits the approval of the Ministry of Health. A scheme for the coördination and extension of the maternity and child welfare and school medical work has been approved, by which the gap between infancy and the school age will be filled by reasonably continuous supervision and the treatment of dental and visual defects and of minor ailments will be adequately met.

Finchley.

Dr. Wilson Jameson thinks that Finchley's greatest need at the present time is a number of small houses containing a living room, scullery, bathroom, and two bedrooms. In the council's housing scheme this type forms less than 9 per cent. of the whole. "Such accommodation," he says, "is suitable for younger married couples and can be let at a figure within measurable distance of an economic rent." Dr. Jameson regrets the resignation of Mr. Mellor, the organiser of physical training, and states that, in the short period of nine months, he was successful in securing the interest and coöperation of both staff and pupils, and that his work will prove of lasting benefit to the schools. He hopes that before long the Finchley education authority will find itself in a position to make this appointment a permanent one.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 1st, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 45; scarlet fever, 1377; diphtheria, 819; enteric fever, 73; pneumonia, 573; puerperal fever, 37; cerebro-spinal fever, 8; acute poliomyelitis, 5; acute polio-encephalitis, 3; encephalitis lethargica, 48; continued fever, 1; dysentery, 6; ophthalmia neonatorum, 98. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 27 from measles, 9 from scarlet fever, 35 from whooping-cough, 16 from influenza, and 18 from diphtheria. There were 101 deaths of children under 2 years from diarrhœa and enteritis, as compared with 61, 50, 41, and 29 in the preceding weeks. In London itself there were 6 deaths from diphtheria, 7 from whooping-cough, and 2 from influenza.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

C. R. Moore, W. J. Doody, and T. F. Crean to be Surg. Lts.

Surg. Comdr. R. B. Scribner is placed on the Retd. List with rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Maj. W. C. Nimmo, from half-pay list, retires on retired pay.

Capt. J. A. W. Ebden retires, receiving a gratuity.

ARMY RESERVE OF OFFICERS.

N. M. Maclennan, late 2nd Lt. 3rd Camerons, Spec. Res., to be Lt.

MILITIA.

Capts. H. Gwynne-Jones, G. E. Pepper, and W. A. Lethem to be Majs.

TERRITORIAL ARMY.

General Hospitals: Lt.-Col. (Bt.-Col.) J. H. Ray resigns his commn. and retains his rank with permission to wear the prescribed uniform.

General List: Capt. G. Moore (from R.A.M.C., T.A. Reserve) to be Capt.

Capt. H. D. Smart, having attained the age limit, is retired and is granted the rank of Maj.

Lt. T. S. Torrance (late Defence Force) to be Lt.

ROYAL AIR FORCE.

Squadron Leader H. Harvey is transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICE.

The King has approved the grant of a temporary commission as Lt. to Berent Narain Khan.

The King has approved the relinquishment of his temporary commission by Capt. Manmahan Shamnath Drulow, who is permitted to retain the rank of Capt., and has approved the resignation of his commission by Capt. A. F. G. Balkes.

KIRKBY MOORSIDE ORTHOPÆDIC HOSPITAL.—On July 31st Princess Mary opened the Yorkshire Orthopædic Hospital at Kirkby Moorside. The building consists of three wings with wards that will accommodate 100 beds; one of them is named after the Rt. Hon. J. R. Ferens, of Hull, who has given generously towards the cost. An operating theatre, a gymnasium, staff quarters, and a refectory have been provided, and the site was given by Mrs. Edward Thaw, of Welburn Manor.

Obituary.

WILLIAM WYNN WESTCOTT, M.B. LOND., M.R.C.S., L.S.A., D.P.H.

THE death is announced from Durban of Dr. Wynn Westcott, well known as one of the most active of London coroners, at the age of 77 years.

William Wynn Westcott was born at Leamington, the son of Dr. Peter Westcott, of Oundle. He was educated at Kingston-on-Thames Grammar School and University College, London, graduating in medicine at London University in 1871, after having taken the M.R.C.S. and L.S.A. a year previously. For ten years he was in general practice at Martock, Somerset, where he was certifying factory surgeon and local secretary of the Sydenham Society, and then came to London as medical officer of health for Islington, an appointment which he shortly relinquished on being chosen deputy coroner for Central Middlesex and Central London. Thereafter for a period of 20 years he acted as coroner for North-East London, during which time he held inquests numbering not many less than 1000 a year. At this time he was admitted a member of the Middle Temple.

With his original mind and outspoken habit, the coroner's court over which he presided became noteworthy for eliciting other important matters than the immediate cause of death in the particular case. At one time he noted that every tenth case he inquired into was a death of an infant while in bed, and the lenient view of an "accident" began to be less general. He was a sharp critic of official death returns, for he had abundant experience of the reluctance of medical men to certify the actual cause where this was due to fault or failing. Simple natural deaths of adults were in his view nearly all due to cerebral hæmorrhage or to syncope consequent on heart disease, but he would have been a bad judge before whom to advance this view when it might conceal more sinister circumstances. He formed the opinion that the best witness in most criminal injuries was the police surgeon of several years' standing, and that in cases of poisoning an analytical chemist was more useful than an expert pathologist. His book on the history and causation of suicide was based on knowledge and experience gained in the court where he had on the average a case a week to investigate. It was a great regret to him that the pathological discoveries of the coroner's court were not systematically recorded and preserved.

Public work outside the coronership occupied much of Dr. Westcott's time. He was one of the first presidents of the Society for the Study of Inebriety, he was a constant attender at the Medico-Legal Society's meetings, and for a long while he was a divisional director of the Red Cross Society in Islington. He collaborated with the late Mr. William Martindale, F.C.S., in the production of the Extra Pharmacopœia which appeared in 1883, and was sold out in a few weeks; and for 18 editions his intimate medico-legal knowledge and his shrewd advice in points of doubt and difficulty were invaluable in helping Mr. Martindale and his son to keep the volume scrupulously up to date as a work of reference. Dr. Westcott was a widely read man who placed his culture freely at the service of others. Quite recently he had contributed papers to the Theosophical Society on such subjects as conscience, prayer, music, and Mohammedan doctrine. He made a hobby of Egyptian and Hebrew antiquities and was an authority on books concerning magic and alchemy, being chief of the Rosicrucian Society of England.

His home life was marred by bereavement. His wife, the daughter of Mr. E. Crawford Burnett, predeceased him four years ago, and of his five children only a daughter survives. Two sons, one qualified in medicine, the other in dentistry, died at the outset of their careers, and he also lost two daughters. His memory will be cherished as one who did much for his time and generation.

GEORGE KENNEDY SMILEY, O.B.E., M.B., B.A.O. R.U.I.

Dr. George Smiley, Regional Medical Officer to the Ministry of Health in the Manchester area, whose death occurred recently at Alderley Edge, was born and educated in Londonderry, entering Queen's College, Belfast, for his first medical training. As a young man he was characterised by the independence of judgment, which marked all his life, while he was known among his student contemporaries as a skilful and daring half-back at Rugby football. He graduated in medicine at Dublin in 1897, went to sea for a year, and then, after a short period in the south of England as an assistant, settled in Londonderry in general practice. Here he grew interested in ophthalmology, and became attached as honorary surgeon to the Eye Hospital of the city, taking out for several years post-graduate courses at Moorfields. In 1906 he married and left Ireland to carry on a practice in Derby, and while here he began his intimate association with the British Medical Association on being appointed secretary of the Derby Division. He was duly elected on the Representative Body and the Council of the Association, and when the National Health Insurance Act came into force became secretary of the Derby Local Medical Committee, and later of the Panel Committee. In 1916 he was chairman of the Medical Benefit Sub-Committee, a position which he held for two years, when his fairness and width of outlook led to his election as chairman of the Insurance Committee.

When the war broke out he found work ready to hand at the depôt of the Sherwood Forresters at Normanton, where he eventually acted as P.M.O., and, though without a commission, his services were later recognised by the award of the O.B.E. About six years ago he contracted an acute sepsis which, after an illness of many months' duration, left him with a damage to his left hand, such as rendered it impossible for him to carry on general practice, so that his appointment upon the Regional Medical Staff of the Ministry of Health, which was particularly well justified by his character and career, was one that he was able to accept with gratification. He was selected to fill the important post of the Manchester area, and soon established himself in the esteem of the insurance practitioners in that city and of his own colleagues in the service. Unhappily signs of serious abdominal mischief showed themselves last year, and while a palliative operation gave him relief, and indeed wonderfully good health for 15 months, the issue was merely postponed. He died on August 2nd, bearing the last two months of his illness with fortitude under the care of a devoted wife, to whom we express our sympathy.

THE LATE DR. S. J. LEONARD.—Stephen Joseph Leonard, L.R.C.P. Irel., L.A.H. Dub., died at his residence, Warrington, on July 31st, in his sixty-ninth year. A native of Galway, he studied medicine at the Royal College of Surgeons in Dublin, where he qualified as licentiate in 1893. For a time he was in practice in Dublin, and then moved to London, where he remained for 20 years as a busy general practitioner. Eight years ago he took over the practice of the late Dr. Adams in Warrington, where he proved himself a highly popular and much respected physician. He leaves a widow and four sons.

THE LATE DR. G. L. L. HAWKEN.—Giles Lockwood Lang Hawken, who died recently at Brighton after a lengthy illness, was a well-known medical practitioner in the Hurstpierpoint district. A Cornishman by birth, he received his medical training at University College Hospital, London, and qualified with the M.R.C.S. and L.S.A. in 1874. He went to Hurstpierpoint in the following year, joining Dr. Holman, and with other partnerships carried on practice for 40 years. For many years he was surgeon to St. John's College, Hurstpierpoint—one of the colleges of the Woodard Foundation—and to the local company of the Volunteer Force. Very popular in the district, he had a wide practice, his cheery manner winning a large circle of friends. He retired about six years ago, and after a few years' stay in Devonshire went to Brighton, where he passed away. He was interred at Cuckfield on August 4th.

"Audi alteram partem."

PERIODIC MEDICAL EXAMINATION.

To the Editor of THE LANCET.

SIR,—I have read with much interest Dr. Otto May's article on Periodic Medical Examination in THE LANCET of Jan. 24th. For some years past in my work at the Children Homes (Detskie Doma) in Temir Khan Schura, about 500 children, I have noted the results of periodical examinations of about 500 children in a book which I call the "Bio-Sanitary Passport." Each child has his own passport, that contains: (1) results of the periodic examination twice a year; (2) changes of health occurring during the year; and (3) the condition of the child's life. If such a passport could be kept from birth and continued until death we should gain: (1) knowledge of the developments and changes of the human constitution; (2) early recognition of character (both physical and psychical), and the possibility of drawing all the advantages of prognosis and prophylaxis.—I am, Sir, yours faithfully,

Dr. A. A. PETROVITCH,
Temir Khan Schura, Dayestan S.S.R., Union of Socialist Soviet Republics (Russia).
July 18th, 1925.

THE ÆTIOLOGY OF CANCER.

To the Editor of THE LANCET.

SIR,—Long years ago, but not many months before Koch showed that tuberculosis was a micro-parasitic disease, I attended a Brown lecture delivered by Sir John Burdon Sanderson. The subject of the lecture was "scrofula," and the eminent lecturer told his audience that scrofula could not be a specific disease because he had collected dust from St. Paul's Cathedral, from Westminster Abbey, and from his own drawing-room; and in each instance the dust when inoculated into a guinea-pig had produced a tuberculous lesion.

It is interesting to compare this experience of mine with the opinions expressed by Prof. Powell White in THE LANCET of August 8th. He writes: "The great majority of pathologists have always recognised that the known phenomena of cancer are incompatible with the theory of an extrinsic specific causal agent. . . . To take one point only, it is now possible to induce cancer in animals without taking thought of any parasite. If an extrinsic parasite is to be considered necessary for the production of cancer, this organism must be present at all times either in all animals or else in the atmosphere."

My friend, the late Prof. Shattock, with whom I had the privilege of working for many years on the intimate pathology of cancer, held "that the parasitic hypothesis of the nature of cancer recommends itself as bringing the essential pathology of new growths into natural relation with other diseases, such as tuberculosis, the parasitic pathology of which admits of demonstration"; and further he believed that the parasitic hypothesis was the only one on which research on cancer could be hopefully based. I need scarcely add that Prof. Shattock was as conversant as any biologist (*pace* Prof. White) with the constitution of living matter. I am, Sir, yours faithfully,

CHARLES BALLANCE.

Harley-street, W., August 10th, 1925.

PERIODICITY OF CHOLERA IN INDIA.

To the Editor of THE LANCET.

SIR,—In reply to Sir Leonard Rogers's letter of June 14th, which refers to my note on the periodicity of cholera in India, I may say that I felt it incumbent on me to make my preliminary announcement as brief as possible. Apparently, however, brevity can be carried too far.

In a Memorandum on the Epidemiology of Cholera, which was written by me at the request of the Health Section of the League of Nations—and which I understand will be published shortly—I have given a more or less complete bibliography of the literature on the subject. H. W. Bellew's book and A. Herbert's work are both included in that bibliography, and are discussed in the Memorandum. The words "no such periodic trend" in my note in your columns were perhaps unfortunate, but referred, of course, only to the six-yearly periodicity, and were not intended to include Bellew's "three-year cycle," which he himself failed to substantiate. I think the last paragraph of my note plainly indicates that the Madras Presidency Public Health Department not only *can* foresee cholera epidemics, but *has* foreseen them in time to prevent disseminations of the disease. It is particularly with regard to the control of pilgrim and festival centres that we have scored our greatest successes.

I agree with Sir Leonard Rogers when he says that there are other conditions giving rise to cholera epidemics "not so simple as any 'three-year' or 'six-year' cycle." "The other work on the same subject" which I alluded to, and which is nearly ready for publication, will deal with a number of those conditions.—I am, Sir, yours faithfully,

A. J. H. RUSSELL,
Major I.M.S.

Madras, July 17th, 1925.

IS THERE A SEASONAL PERIODICITY IN SERUM RASHES?

To the Editor of THE LANCET.

SIR,—I do not think that the solution of this question is quite so simple as my friend, Dr. Brownlee, would have us believe. Some years ago (THE LANCET, March 2nd, 1918) you were good enough to publish certain tables, prepared by me, by which it was shown that the incidence of serum rashes varied with the age and sex of the patient. Other factors, besides age and sex, have to be taken into consideration—namely, the volume of serum injected (which may explain the age-incidence), the source of the serum, the quality of the serum—that is, whether it is whole or whether it has been refined—and, last but by no means least, the accuracy of the records. I confess to being horribly suspicious of those scanty rashes in July, August, and December in Table I. of Dr. Brownlee's letter. Those months are seasons of holidays and temporary assistant medical officers.

It so happens that some months ago I got out—with quite a different object—the figures for the North-Western Hospital for the years 1922 and 1923, in the same form as in Dr. Brownlee's Table I. Here they are, as in his Table II., with the exception of the theoretical number, which I, being no mathematician, am unable to supply. Perhaps he will do so.

—	Cases.	Rashes.	Percentage of rashes.
Jan.-March ..	539	225	41·7
April-June ..	354	147	41·5
July-Sept. ..	385	161	41·8
Oct.-Dec. ..	466	229	49·1

Dr. Brownlee appeals for information to those who possess it. Well, there are the records of over 20 years at the Eastern Hospital, Homerton, and of five years at this, the North-Western Hospital, Hampstead, of which, I am sure, the Metropolitan Asylums Board would allow him to make use, and for the accuracy of which I can vouch, so far as hospital statistics can be accurate.

I do not dispute the importance of the question in respect of the epidemiological points referred to by Dr. Brownlee.—I am, Sir, yours faithfully,

E. W. GOODALL.

North-Western Hospital, Hampstead, August 9th, 1925.

FAMILIAL ABDOMINAL LESIONS.

To the Editor of THE LANCET.

SIR,—I read with much interest the article by Mr. G. P. B. Huddy in THE LANCET of August 8th. He assumes that in certain families a type of stomach exists that either anatomically or functionally produces gastric or duodenal ulcer or carcinoma. Is it not at least equally, or more likely, that the familial factor, which one can admit, is concerned with diet, more particularly, as he suggests, with bad teeth, which again are possibly if not probably the result of diet? My own family history would appear to support his thesis. My maternal grandparents reared 13 children. Of these four (all females out of a total of six) suffered from stomach disease. My mother suffered from gastric ulcer for the last four years of her life, with indigestion and hæmatemesis, and died probably (almost certainly) of gastric cancer. An aunt died of hæmatemesis, another of perforated gastric ulcer, and a fourth suffered from severe attacks of melæna and indigestion. This was a long time ago, and I do not know if they had good or bad teeth, *but* I do know that as children and young adults they drank well water, and it was the family practice at the end of a meal to put salt in their tumblers and count "heads" of the visible animalculæ so killed. *This in a doctor's house!* Personally I regard the cause of ulcer as being due to sepsis. I cannot remember seeing a case of chronic ulcer with a clean mouth of natural teeth, though I have seen them in cases where carious teeth have been removed and a false set substituted after the ulcer had occurred.

While on this subject I may perhaps be allowed to add the following interesting fact. Yarmouth is annually visited by a large number of the Scotch fisher-folk; it is an unquestioned fact among the members of our hospital staff that with their arrival there is a greatly increased rate in the admissions for perforated ulcers. I should say that we usually get three or four admitted during the season of three months. I myself had three cases last fishing. What the factor is is only guesswork, but they are great salt eaters, and the girls drink the brine out of the barrels. Also they are perforce uncleanly in their habits and their teeth are not good.

I am, Sir, yours faithfully,

R. LEONARD LEY, M.B., B.C. Camb.

August 10th, 1925.

PS.—In regard to my mother's family, the boys all, as far as I know, escaped stomach trouble, yet the relative incidence in males is much greater. The boys would be more often away from home and would and did leave home earlier. This points very strongly to the foul well water being the causative factor.—i.e., sepsis.

THE SITE OF BETHLEM HOSPITAL.—The governors of Bethlem Hospital have offered to present five acres of the site to the London County Council as an open space. Of the total of 11 acres, which will be vacated by the transfer of the hospital to the Monks Orchard Estate, about three are occupied by the buildings.

WORK AND FINANCE OF ST. BARTHOLOMEW'S HOSPITAL.—In 1921 the excess of ordinary income over total expenditure was £9535; the ordinary income was £181,805. The in-patients numbered 9208, and their average stay was 23·78 days; the first attendances of casualty patients numbered 67,000; 2781 cases of street accidents or illness were brought in—nearly eight a day. Since the additional accommodation required cannot be provided on the site the governors have bought for £51,203 premises in Charterhouse-square and Charterhouse-mews suitable for the housing of a large portion of the nursing staff. The first block of the new nursing home has cost £96,000, and the further section now being built will entail additional expenditure of £87,000. The nursing staff numbers 321, which is insufficient to allow for holidays, illness, and emergencies, and a material increase is contemplated. Meanwhile the governors report "a marked decrease" in the number of applications for general training. The hospital's laundry work cost £7883, and more than a million and a quarter pieces were washed during the year.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly Final Examination of the Conjoint Board, held from July 7th to 31st, the following candidates were approved in the undermentioned subjects:—

Medicine.—R. B. Alston, St. Thomas's; W. A. Ball, King's Coll.; F. G. Beauchamp, Birmingham; J. M. Brodrick, Liverpool; Irene F. Callender, St. Mary's; J. P. Carpenter, Birmingham; W. S. Chapman, Univ. Coll.; Dorothy A. Chown, St. Mary's; G. Coope, Manchester; P. F. S. Court, Guy's; Anne A. Craig, Royal Free; A. C. Dalzell, King's Coll.; May W. de Livera, Ceylon and Royal Free; H. V. Dicks, St. Bart.'s; J. Dockray, Cambridge and St. Bart.'s; Marjorie M. Duggan, Cardiff; G. H. Dymond, St. Bart.'s; J. Evans, Guy's; J. P. Evans, Charing Cross; M. M. Fikri, Cairo; G. W. S. Foster, St. Bart.'s; A. C. Gairdner, London; S. E. Gawthrop, Durham; A. P. Gorham, Bristol; G. J. Gregerson, Adelaide and London; R. N. Hall and L. J. Haydon, St. George's; Kathleen M. Horton, London; J. P. Huins, Birmingham; J. W. Jeffery, St. Mary's; Mary Jennings, Royal Free; D. M. Johnson, and G. L. C. Jones, St. Bart.'s; Adele A. Kahan, L. C. Kalra, and H. Kesselson, Charing Cross; R. H. Knight, St. Bart.'s; Alice B. Laker, Charing Cross; T. P. Lalonde, Bristol; A. H. Levers, Westminster; S. Levy-Simpson, London; G. M. D. Lobban, Leeds; Mary C. Luff, Univ. Coll.; I. H. Mackay, Sydney and London; Nancy S. Marshall, St. Mary's; S. Mellins, Middlesex; P. B. P. Mellows, St. Bart.'s; D. G. Morgan, Cardiff; Margaret E. Morton, Royal Free; Gertrude M. Nicholson, Durham; T. C. Oakley, Birmingham; S. C. St. G. C. Parry, Middlesex; F. B. Parsons, St. Bart.'s; L. B. Phillips, Bristol; H. P. Pieris, Madras and Middlesex; O. L. Prosser, Liverpool; R. L. Quilliam, King's Coll.; L. D. Richards, Charing Cross; Bertine M. Rix, St. Mary's; Alice L. Robson, Royal Free; E. J. Rubra, Westminster; A. G. Schroeder, Adelaide and London; J. W. Shackle, Guy's; Sara C. A. Sharpe, St. Mary's; E. V. Slaughter, Middlesex; E. Sorabjee, Guy's; A. W. E. Soysa, King's Coll.; A. W. Spence, Cambridge and St. Bart.'s; R. K. Stockbridge, Adelaide and London; R. G. Strouts, London; B. R. Sworn, St. Thomas's; A. G. S. Tabb, Charing Cross; G. M. Tanner, St. Bart.'s; Elizabeth L. Taylor-Jones, Royal Free; E. J. E. Topham, St. Bart.'s; I. Vitenson, London; W. N. Welinkar, Middlesex; H. L. Wilson, St. Bart.'s; Jessie Wiltshire, Univ. Coll.; F. G. Winterton, St. Bart.'s; J. Wiseman, Guy's; and Rosa S. Wordsworth, Charing Cross.

Surgery.—Y. Abdel-Messiah, Middlesex; A. R. Adderley, St. Thomas's; P. W. A. Agnew, St. George's; R. M. Ainsworth, Liverpool; V. M. Albuquerque, King's Coll.; C. R. Alderson, Univ. Coll.; R. C. Amies, St. Thomas's; E. N. C. Annis, Guy's; S. A. Antoun, Birmingham; H. Y. Awad, St. Thomas's; H. Aziz and Marion L. Bainbridge, Manchester; J. C. H. Baird, St. Bart.'s; D. G. Balakirsky and A. L. Banks, Middlesex; J. V. Bannehr, S. B. Benton and W. F. D. Benton, St. Bart.'s; E. I. Bieber, Liverpool; C. E. Bigger, St. Thomas's; A. D. Blackwell, Middlesex; Ellen W. M. Bridge, Manchester; W. Buckley, London; F. Bunje, St. Mary's; Lillie M. Burton, Manchester; De L. Carey, St. Mary's; W. S. Chapman, Univ. Coll.; B. Chaudhuri, Middlesex; W. F. Cooper, St. Bart.'s; P. F. S. Court, A. R. Cox, and P. C. Cumber, Guy's; P. E. J. Cutting, St. Bart.'s; S. D. Dalal, Bombay; E. A. Darukhanawalla, Middlesex; S. W. Davies, Cardiff; Winifred de Kok, Royal Free; G. C. Dewes, St. George's; Mary G. H. Dickson, King's Coll.; G. Dignam, Manchester; W. H. Dowell, Guy's; I. A. Evans, Cardiff; O. F. Farndon, R. R. Fells, and P. H. Flockton, St. Bart.'s; R. M. Forsayeth, London; S. W. Gabbe, St. Thomas's; S. E. Gawthrop, Durham; J. F. E. Gillam, St. Thomas's; B. M. C. Gilsenan, St. Bart.'s; Z. A. Goma, Birmingham; E. P. Gough, St. Bart.'s; S. E. Goulstine, Durham; D. P. Gray and W. H. Green, Middlesex; L. A. N. Greenway, King's Coll.; H. W. Greenwood, Middlesex; Margaret H. Greg, Royal Free and Manchester; J. C. P. Grey, St. Thomas's; H. R. Griffin, Middlesex; B. J. Griffiths, Cardiff; G. J. Gross, King's Coll.; K. H. A. Gross, St. George's; W. S. Grove, Guy's; F. P. Guilfoyle, St. Bart.'s; C. W. Harrison, Los Angeles and St. Bart.'s; A. Hobson, Birmingham; D. P. Holmes, Westminster; R. L. Holt, Manchester; L. E. Houghton, Guy's; S. Howard, London; Ruth T. Hurnard, Royal Free; I. A. Jackson, Guy's; E. D. Jones, St. Bart.'s; J. Kahanas, Berne and London; W. R. Kirkpatrick, Guy's; P. H. Knowles, Bristol; S. N. Lahiri, St. Andrews Univ.; M. E. Lampard, King's Coll.; C. G. Le Couilliard, Middlesex; A. H. Levers, Westminster; H. M. Levy, Middlesex; S. Levy-Simpson, London; D. W. E. Lloyd, Guy's; A. J. McMillan, Middlesex; F. G. Martin, Charing Cross; R. G. Mathews, Univ. Coll.; Clara Mendelssohn, Westminster; R. D. Milford, St. Thomas's; D. E. J. Mitchell, Manchester; F. E. Montague, St. Thomas's; C. M. Moody, St. Mary's; P. Morton, London; D. H. P. M. Q. Mylechreest, St. Thomas's; T. K. Natesan, Madras and London; C. E. Nicholas, London; H. E. Nourse, Middlesex; Eileen A. Nugent, Royal Free; T. C. Oakley, Birmingham; E. J. O'Keeffe, London; C. J. S. O'Malley, St. Thomas's; A. Orlansky, Middlesex; C. H. Parker, London; G. E. G. Peirce, St. Mary's; W. G. Porter, Guy's; Winifred E. Probert, Westminster; F. W. F. Purcell, St. Thomas's; Marjorie D. Reddan, Royal Free; A. M. Rhydderch, London; L. D. Richards, Charing Cross; R. I. Roberts, Manchester; P. H. Rossler, Lausanne and Zurich; D. J. L. Routh, Univ. Coll.; I. J. Sachs, Middlesex; M. Schwartz, Univ. Coll.; S. T. Seccombe, St. Thomas's; J. Silverstone, Westminster; H. J. Simmons and K. S. Smith, Middlesex; R. E. Smith, Guy's; J. Spencer, St. Bart.'s; F. E. Stabler, Durham; H. B. Stallard, St. Bart.'s; C. A. Stanley, St. Thomas's; A. F. H. Stewart, Guy's; Mary Stirk, Manchester; Stella C. C. Stuart, Royal Free; E. D. THE LISTER WARD AT GLASGOW ROYAL INFIRMARY —The famous Lister Ward, which was pulled down last year, has been "re-edified" at the Wellcome Historical Medical Museum in Wigmore street The walls and contents of the ward have been preserved and reconstructed, and the original fireplace and equipment transferred This equipment includes the central pillar and round table, Lister's sterilising apparatus, and the actual beds in use in his time

LONDON (R F H) SCHOOL OF MEDICINE FOR WOMEN (UNIVERSITY OF LONDON) —At recent examinations the following awards for 1925–26 have been made:—Sarah Holborn Scholarship: Miss Mary Gould; Dr Margaret Todd Scholarship: Miss M M White; School Jubilee Bursary: Miss O N Grant; Flora Murray Bursary: Miss H E. Newman; Alfred Langton Scholarship: Miss G V Smallpeice; Mabel Sharman Crawford Scholarship: Miss E. T Moss; Helen Prideaux Post Graduate Scholarship: Miss Gladys Hill, M B, B.S; St Dunstan's Medical Exhibition: Miss E. M G Stevenson; Mrs. George M. Smith Scholarship: Miss G B Castle; Isabel Thorne Scholarship: Miss Maureen Evans.

DONATIONS AND BEQUESTS —The late Mr G Collis, of The Wick, Richmond Hill Surrey, left by will, among other bequests, on his wife's death, £500 to the Croydon General Hospital and £500 to the Royal Hospital, Richmond —By will the late Surgeon Lieut. Colonel Heinrich Friedrich Lawaetz Melladew, Royal Horse Guards, left £1000 in memory of his late wife and her brother, Judge Bain, to Winnipeg Hospital towards the provision of an X ray outfit for the hospital; £500 to St. Dunstan's work for Blinded Sailors and Soldiers; and £500 to the Children's Country Holiday Fund —Under the will of the late Mr John Douglas Oliver, of Dacre-street, Morpeth, the testator left, on his wife's death, £3000 to the Morpeth Cottage Hospital and District Nursing Association.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION —At Queen Mary's Hospital, Stratford, there will be an intensive course embracing general medicine, surgery, and the specialties from August 24th to Sept 3rd The sessions will begin either at 10 or 10.30 A M and continue until 5 P M. In September a variety of courses will be held—viz., Diseases of the Chest at the Brompton Hospital Sept 21st to Oct 3rd; Diseases of the Skin, Blackfriars Hospital, Sept 7th to 19th, also the same date a course at the Infants Hospital; Ophthalmology at the Royal Westminster Ophthalmic Hospital, Sept 7th to 26th; a series of weekly lecture-demonstrations in Electro-therapy at the Royal Free Hospital, Sept 23rd to Oct 11th, and a general course in medicine, surgery and the special departments at the Westminster Hospital from Sept. 21st to Oct. 3rd Copies of the syllabus of each of these courses may be obtained on application to the Secretary to the Fellowship of Medicine at 1, Wimpole-street, London, W 1

Appointments.

GREENWOOD A C M R C S L R C P Lond has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Horncastle District of the County of Lincoln

Vacancies.

For further information refer to the advertisement columns

Birmingham University—Lecturer in Bacteriology £150
Bradford Royal Infirmary—Two H S's Each £200
Bristol General Hospital—H P's, H.S, &c Each at rate of £80

Plymouth Borough—Asst M O H £600
St Peter's Hospital for Stone, &c, Henrietta street, Covent Garden, W C—H.S at rate of £75
West Riding County Council—Dist Tub O for Barnsley £600

Births, Marriages, and Deaths.

BIRTHS.

DAVIDSON —On August 4th and 5th at 84, Bickenhall mansions, Gloucester place W, the wife of Maurice Davidson M D, of two sons (twins)

HEPPER.—On August 7th at Felnley, Surrey, the wife of Dr John E. Hepper of a son

MARRIAGES

BOWIE—WILSON —On August 1st at the Barclay Church, Edinburgh Major John Darling Bowie, D S O, R.A M C, to Winifred Margaret, daughter of the late John Wilson and Mrs Wilson of Braidwood, Corrennie gardens Edinburgh

CARTER—WESTMACOTT —On August 5th, at St Martin in the Fields Ernest Edwin Carter M B, B S, to Eileen Helen Maude Westmacott second daughter of the late Colonel H R Westmacott Welch Regiment, and Mrs. Westmacott, of Woodside Ashley, Hants

SIMPSON—BATTEN On August 5th at St Mary Abbot's Kensington Reginald Hugh Simpson, M D, M R C P, to Joyce Rayner Batten M B, B Ch younger daughter of Dr and Mrs Rayner Batten, of Campden Lodge, W

DEATHS.

ATKINSON —On August 6th from pneumonia Dr Arthur William Atkinson of Mirion House, Crewe

DANIEL —On August 2nd, at Beaminster, Dorset Thomas Palmer Daniel M R C S, in his 80th year

DUKE.—On July 22nd at Kenman, Victoria B C, Valentine de Saumarez Duke, L.R.C.S Irel L.K Q C P Irel, formerly of Nuwara Eliya Ceylon aged 70

JOHNSON —On August 9th, at 4, Heath hurst road Hampstead Florence the dearly beloved wife of Dr Rance Johnson

KELLETT —On August 3rd at Waterloo-road, Bedford, Leonard Henry Kellett M D, Inspector General R N retd, aged 73 years

WYNNE.—On August 4th, at Killard, St Martin's, Guernsey, John Darley Wynne M B., son of the late Frederick Wynne Bishop of Killaloe

N B —A fee of 7s 6d is charged for the insertion of Notices of Births Marriages, and Deaths

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THE FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, Wimpole-street, London W

MONDAY August 17th to SATURDAY, August 22nd —ALL SAINTS HOSPITAL, Vauxhall Bridge road, S.W Clinical demonstrations Wednesday evening Thursday afternoon and evening, and Saturday afternoon Wed 2 P M, Mr H E. Griffiths on Neoplasms of the Testis —QUEEN MARY'S HOSPITAL FOR THE EAST END Stratford Intensive course in General Medicine, Surgery and the Specialties. First week as per syllabus Morning and afternoon sessions

INDEX TO "THE LANCET," VOL. I, 1925.

THE Index and Title-page to Vol. I, 1925, which was completed with the issue of June 27th, is now ready A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2

THE LANCET: SUBSCRIPTION RATES.

Notes, Comments, and Abstracts.

MEDICINE AND SCIENCE AT WEMBLEY.

A visit to the British Empire Exhibition at Wembley may be made the occasion of a useful study of public health and the applications of science to human need.

The Ministry of Health has issued a guide (price 3*d.*) to its exhibits in H.M. Government Pavilion, where the first hall is occupied with an historical sketch of the medicine-man with his amulets and charms, and the alchemist with his alembics, in contrast with the equipment of the modern laboratory. The exhibits illustrate the progress in the campaigns against malaria, leprosy, plague, and louse-borne diseases and in the technique of port medical work. In the second hall is a model of the Lister Ward and of a modern operating theatre, along with examples of water purification and sewage disposal, while the third hall contains well-thought-out schemes of applied medicine in municipal affairs, including housing, child welfare, industrial disease, pure food, and clean milk.

A second edition has now been issued of the handbook[1] to the exhibits of the Royal Society, which itself is worth the whole of an afternoon visit. This book is compounded of essays by some 24 distinguished scientific men in illustration of the demonstrations which are on view and of the progress of natural knowledge: it is not in any sense a glorification of modern science as the handmaid of technological success. The result is admirable, though naturally to each reader some of the sections will appeal more than others. About a third of the whole is taken up with the structure of matter and radiation; there must be many readers of The Lancet, in whom X rays, ultra-violet light, and wireless have surprised an imperfect knowledge of modern physics, and they will find the diagram of the range of various electro-magnetic waves, which forms the frontispiece, well worth the modest price of the volume. Dr. Simpson on the water in the atmosphere and Dr. Tate Regan on Darwinism strike particularly good notes as essayists, and it is pleasant to find Prof. Poulton still standing on the impregnable rock of natural selection in his short discourse on mimicry.

Commercial Exhibits.

Many of the series of exhibits in the Chemical Section at Wembley, organised by the Association of British Chemical Manufacturers, are well worth the inspection of clinical medical men; there may be no special appeals to medicine or therapeutics save in a few directions, but to preventive hygiene there are many. Such matters as the materials for house construction and their preservation, for road manufacture, for paving and for fire-proofing are of growing importance to doctors, as questions of domestic accommodation, sanitary environment, and convenient transport become more intimately associated with public health. Such stalls as those of Messrs. Albright and Wilson, Messrs. Brunner Mond, Messrs. Chance and Hunt, and Messrs. Naylor Brothers can be studied with advantage, while the products exhibited by the Gas Light and Coke Company and the South Metropolitan Gas Company will be also found of practical interest.

The fine display of Messrs. Burroughs Wellcome is of considerable historic interest to medical men. At the stand of this firm, and still bearing the dents of hard usage and particles of earth from the world's highest mountain, a relic of the Mount Everest expeditions of 1921, 1922, and 1924 may be seen—it consists of the "tabloid" medicine chest as supplied for use in these huge adventures. The medical officer in charge of each of the expeditions has sung the praises of this chest, which in 1922 travelled over 1000 miles by yak transport—the most trying in the world, and has served for three successive expeditions. It is still fit to do duty with a fourth. The case which accompanied R 34 in the first airship flight from England to America and back is also shown, prompting the representatives of the firm to anticipate a distant time when leviathans of the air will carry their own physician and medicines for a passenger list approaching in length that of a Victorian liner. Here also is the actual tube of solidified ginger essence, one of the four phials of "tabloid" medicines, which Peary carried in his last dash to the North Pole. Here are the cases which Amundsen and Scott carried to the South Pole in 1911–12. One case bears in Amundsen's handwriting the inscription. "Sydpolem, 14-12-1911." The other is sadly devoid of inscription. What may be termed "the explorers' corner" in this display also contains dioramas of the following pioneer events: Stanley crossing darkest Africa, the final attempt to climb Mount Everest, Bleriot flying the Channel, Alcock flying the Atlantic, Ross Smith on the final stage of his flight to Austr[illegible] U.S.A. [illegible]don: world-flight airmen arriving at Croydon. In every instance the original "tabloid" medical equipment which served these pioneers on their travels is shown.

At the stand of the Clayton Aniline Co. everything is designed to remind us of the discovery which led to the manufacture of aniline on a commercial scale, and gave the first impetus to the development of the colour industry. This was in the "fifties" of the last century, and in 1875 the Clayton Aniline Company, Limited, was founded for the manufacture principally of aniline oil and salt. Ever since the company has added to its activities, more or less as a natural outcome, the manufacture of dyestuffs. Although at first aniline was used almost exclusively as the starting-point in the production of synthetic dyestuffs, only a small proportion of the total dyes now produced are actually derived from aniline, but the term "aniline dyes" is used as a popular expression to cover practically all coal-tar intermediates and dyes. The Clayton Aniline Co.'s exhibit does not rely only on the number of colours shown, but calls attention to the evidence supplied of the accumulated knowledge of years of research and experience in a most intricate industry. Some 250 dyes appear of various hues and shades, and are shown in their application to cotton, woollen, silk and artificial silk fabrics, leather, and paper. There are colours for practically all industries, textiles, leather, glass, rubber, and paper, each providing opportunities for the chemist. The Clayton Aniline Company also shows the products manufactured in England of the "Ciba" brand pharmaceutical specialties, one of which, "Phytin," is symbolised at the stall in an attractive statuette, the work of Miss Phyllis Mott. Cases are being shown of Dial, Didial, and Elbon "Ciba" tablets, of other products whose therapeutic effects have been noticed in our columns, such as Lipoiodine "Ciba" tablets and Digifoline tablets—this last being a preparation of vegetable origin, containing the glucosides of digitalis leaf in their natural proportions, free from inert or harmful extractives.

A large range of technical products is displayed by various firms whose names are widely associated in the public mind with activity in the production of bleaching powders or perfumes. Among these are Messrs. Boake Roberts and Co., who show, in addition to many essential oils and terpeneless oils used in perfumery, a range of sulphur dioxide salts with a wide technical application, and a recrystallised menthol which conforms to B.P. requirement. The Castner-Kellner Alkali Company issue a number of interesting pamphlets upon chlorine derivatives and products in relation to public health; the Erasmic Company, Ltd., show many samples of scented preparations in a striking colour scheme; Messrs. J. and E. Atkinson show a complete range of toilet preparations; Messrs. Thomas Fell and Co. specialise in pot-pourri; the Graesser-Monsanto Chemical Works include on their stall some fine specimens of phenol and cresol derivatives; the various employment of hydrogen peroxide inspire the exhibits of Messrs. B. Laporte, Ltd.; bismuth salts occupy a prominent position at the stall of Messrs. Thomas Tyrer and Co.; the stand of the United Alkali Co., Ltd., indicates the various products of the company both in heavy and refined chemicals and in dye products; Messrs. Edwards and Gritton call attention to their medicinal paraffin prepared from Russian petroleum; the Electro-Bleach and By-products, Ltd., show high grades of bleaching powder and caustic soda, as well as Sesqui carbonate of soda, and samples of anhydrous ferric chloride and an especially fine carbonate of lime; and Messrs. Grieve and Gordon make a feature of eucalyptus preparations. Messrs. Charles Roberts and Co. exhibit models of standard tank wagons for the conveyance of all forms of chemical liquids.

Messrs. G. M. Taylor show a fine range of artificial eyes, sadly required in post-war days; and Messrs. Baird and Tatlock, at a stand fitted by the firm's own men, and made at their own works, demonstrate the materials used by them in fitting up laboratories. The finish is that normally used in laboratories, and the same type of benches and finish are in use in the modern laboratory exhibited by the Ministry of Health.

The apparatus on view, it will be seen, covers a wide range from chemistry to psychology, from mechanics to bacteriology.

An Overcrowded Mental Hospital.—The Commissioners of the Board of Control state that the Salop Mental Hospital, upon which otherwise they report favourably, is overcrowded. The accommodation is for 313 males and 388 females, but the average number resident during the past year has been 317 and 421 respectively. The construction of the building will not allow of proper classification, and the Commissioners say that the hospital can only be brought into line with similar institutions of more modern construction by the erection of an admission hospital with cottages for recovering and convalescent [illegible] The accommodation for nurses is "far from ideal."

SOME

Practical Considerations

IN THE CONSERVATIVE TREATMENT OF FRACTURES OF THE PELVIS AND LOWER EXTREMITY.*

A Course of Four Lectures delivered for the University of London at St. Bartholomew's Hospital

By Sir WILLIAM I. de COURCY WHEELER,
M.D. Dub., F.R.C.S. Irel.,
PAST PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

LECTURE II.

The views of the older writers on the subject of injuries to bones are worthy of study. In the process of literary excavations we come across some useless débris, but here and there are found nuggets of pure gold.

Fractures of the Neck of the Femur.

Astley Cooper, whose investigations are so imposing in the history of the surgery of bones, explicitly states that in all cases of *transverse fracture* of the neck of the femur which he has had the opportunity of examining, he has never seen one in which there was union by bone. "The dissections which I have made," says this illustrious surgeon, "have convinced me that *fracture of the* neck of the femur, when it is situated within the capsule, is never united by bone. The union is solely effected by *means* of ligamentous substance, as in fracture of the patella." "This celebrated surgeon," says Dupuytren, "has since *modified* his opinion, as we find him remarking that, as a general rule, fracture of the neck of the femur within the capsule is united by ligament and not by bone, as in the case of the olecranon and the patella, but that it would be a rash assertion to deny the possibility of ossific union, and to maintain that the general rule laid down admits of no exception."

This was more or less *the teaching* up to our own time. Fifteen years ago I treated an aunt of my own, aged 70, in a plaster case with abduction and internal rotation, and obtained bony union.

One of the first statements made by Dupuytren, in an essay on *fractures of* the femur, is that he never saw a fracture of the neck of the femur in a child. We know now this is not uncommon, and after such a statement we wonder whether it is worth while referring back to authorities of the pre-X ray era. The reason I *do so is this*—that credit must be given to Dupuytren for anticipating to some extent the modern work of Whitman, Jones, and other *authorities* for whom we all have such deep respect.

Dupuytren points to specimens in the Museum of the Faculty of Paris and of the Hôtel-Dieu, where numerous examples of intracapsular fractures united by bone are to be found, and *states that* he regarded osseous union of intracapsular fracture of the neck of the thigh bone as demonstrated beyond doubt. He disproves *and* discounts all arguments advanced at the time against the possibility of bony union. He denied that the upper *fragment* was devoid of sufficient blood-supply, and showed that the vessels passing to the head via the ligamentum teres were sufficient. The importance of the ligamentum teres in preserving the viability of the head of the femur has been established *beyond* doubt by Bonn.[1] Dupuytren showed that the neck of the femur is not devoid of periosteum, as stated by some contemporaries, *and that* the bathing of the fragments in synovial fluid could not be a determining factor in *connexion with non-union, as it does not* affect the union of fractures into other joints.

But then comes this significant statement. "The fact is, that the great difficulty lies in the perfect and accurate adjustment and relation of the fractured ends of the bone," and he insinuates that if this can be accomplished bony union may be expected. He *was a shrewd observer, for he realised that* union in this situation must be slow, and suggests as an axiom that fractures of the neck of any bone should be kept at rest twice as long as ordinary fractures of the same bone, and even after that period displacement might occur.

He does not seem to have realised the full importance of abduction, but his *description of the reduction of* a fracture indicates that he was not oblivious to its significance. He describes his procedure thus: "The patient being placed on his back, and the pelvis being fixed by assistants, I bend the thigh on *the belly by raising it, and* then gently draw it from the body, the knee being at the same time flexed. This is immediately followed, without difficulty or the employment of violence, by the limb resuming its natural length and the foot its normal direction." By flexion he relaxed the adductors which produce eversion of the foot, and the glutei and others which draw upwards the *shaft of the* bone. He adopted the principle of Percival Pott, who introduced the flexed position of limbs in the treatment of fractures generally. He designed a double inclined plane splint, the thigh being fixed at nearly a right angle to the pelvis and the leg forming a similar angle with the thigh. He says by this method union takes place without shortening, and quotes *some convincing* cases.

Although abduction is the essential feature in the treatment of fractures of the femoral neck, the arguments of Dupuytren in favour of the double inclined *plane are impressive. His* reasoning is so persuasive that I wonder why this old method fell early into disuse and was supplanted by so unsatisfactory a treatment as weight-and-pulley extension. If there is any one thing I am proud of in the *treatment of fractures* over the last 25 years, it is this—I have never used a long Liston splint, and I have never treated a fracture *of the neck of the* femur by Buck's extension.

It is interesting to note that in 1921 Moore contributed an article in the *Boston Medical and Surgical Journal* recommending that the fracture be reduced under an anæsthetic, and the *leg put* up in right angle flexion of both hip and knee in a plaster cast. In this way the patient can sit up and be moved about in a wheeled chair from the very first. Out of 42 cases so treated by this method, the average age of the *patients being* 65 *years*, 60 per cent. gave a good result.

If the thigh is flexed at right *angles* with the abdomen and the knee at the same angle with the thigh, the relaxation of the muscles tends to prevent *shortening*, and any progressive power of contractility which follows after this position is assumed cannot assert the *direct pull* which produces shortening when the limb is extended. Flexion of the leg corrects eversion of the foot, as was pointed out by Dupuytren in 1810, and again in an excellent paper by Russell as recently as January, 1924, in which he says: "That upward lifting of the bent knee is the natural way of inverting the limb when we wish to correct eversion. Instinctively we first bend the knee and then lift it upwards. The practical fact is that eversion gives no trouble."

Fractures of the Neck of the Femur in Children.

First importance attaches to the partial fracture-separation of the epiphysis of the head of the femur. The condition is most often found in or about puberty, more often in boys than *in girls*. It may arise out of some comparatively trivial and forgotten trauma. Any displacement which occurs may be gradual, the diaphysis yielding in an upward direction and becoming gradually rotated outwards in relation to the head. Solid union takes place, leaving behind a traumatic coxa vara.

---

* All the cases referred to were illustrated by lantern slides. Lecture I. was published in The Lancet of August 15th, p. 313, and Lectures III. and IV. will appear in subsequent issues.

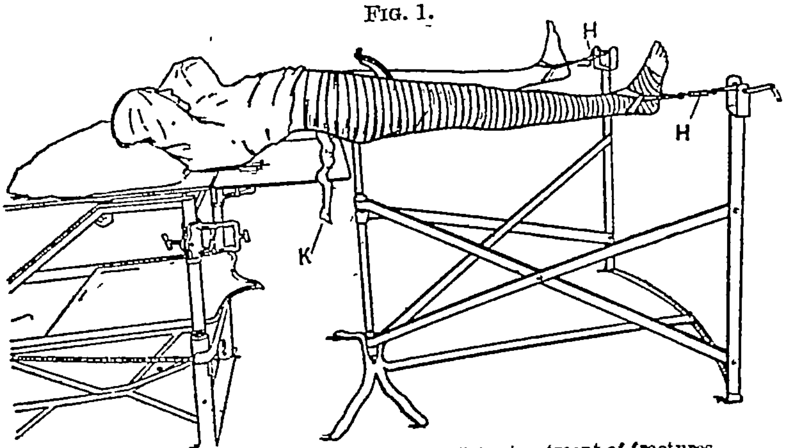
[1] Arch. f. klin. Chir., 1924.

It is a difficult injury to diagnose early, even with the help of X rays, and Sir Robert Jones says it is the most often overlooked of all hip injuries, even by extremely good surgeons. It is suspected when rotatory movements are extremely painful, and when abduction beyond a short range is impossible. There is, at first, no shortening, and the symptoms disappear with rest, but later on, when activities are resumed, shortening occurs, and separation of the epiphysis, partial or complete, will be then recognised. In contrast to this, there may be a complete separation of the epiphysis, a fracture through the neck, or a fracture involving both neck and epiphysis.

Whitman calls special attention to fracture of the neck of the femur in children. The fracture occurs after traumatism to the hip, probably more frequently than separation of the upper epiphysis. It is generally impacted or of the greenstick variety, but the signs and symptoms are much the same. The immediate results are good, but yielding at the point of fracture will produce a coxa vara if the limb is not protected from weight-bearing for many months by a calliper splint. The immediate treatment, whatever the position of the fracture may be, is the same as in adults. Shortening and eversion must be reduced, with subsequent fixation in the position of abduction.

To obtain reduction; flexion and inward rotation followed by traction and abduction, or abduction alone, are required. Seven cases of ununited fracture of the femur in early life are mentioned by Whitman, to prove that non-union may follow this injury in childhood if the treatment is inefficient. Thus he shows that non-union is not accounted for by deficiency of blood-supply, nor by advancing years, but by inefficient treatment. Plaster-of-Paris fixation is the best, and after six or eight weeks the child may be allowed to walk on a calliper splint for two or three months. If the fracture is diagnosed and no displacement has occurred, a short period of rest followed by ambulatory treatment with a calliper splint is sufficient.

FIG. 1.

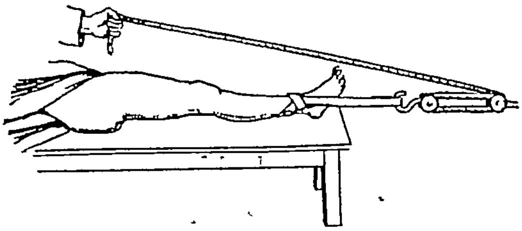


Simple orthopædic table (designed in 1905) for treatment of fractures.

Fractures of the Neck of the Femur in Adults.

I do not think, from the point of view of treatment, that it is necessary to say more than this—that if, in a strong adult, a fracture is impacted, and there is more than half an inch shortening with eversion of the foot, the impaction should be forcibly broken down under an anæsthetic, the deformity reduced, and the treatment carried on as in unimpacted cases. Rotation outwards of the foot matters much more than a little shortening. If the foot is in good position without any outward rotation and the shortenening is inconsiderable, then it is not necessary to disimpact. If there is impaction in an old person, all the circumstances must be carefully weighed before the impaction is broken down to reduce moderate deformity; but it must be remembered that the so-called impacted fracture from indirect violence in elderly people is very incomplete, and functional disability will certainly follow weight-bearing in the absence of proper reduction. A decision must be made as to whether, in an exceptional case, the risk of reduction and fixation is too great. Under such circumstances, crippling, non-union, and deformity must be the result, mitigated to some extent if a calliper splint can be worn.

FIG. 2.



Block and tackle extension (Jones).

The object of treatment of this, as of all fractures, is to restore the symmetry of the broken bone, thus eliminating the primary cause of non-union, deformity, and loss of function. Henderson states that of 120 cases of ununited fracture of the hip seen at the Mayo Clinic, not one had received proper treatment at the time of the injury.

The modern treatment can be summarised in one sentence—reduction of the deformity and fixation in the abducted position. Whitman deserves due credit for insisting upon these conditions. Abduction is checked by tension on the capsule, by contact of the upper border of the neck with the rim of the acetabulum, and of the great trochanter with the side of the pelvis. In abduction the neck of the femur is normally in a horizontal position. In fracture of the neck the fractured end of the proximal fragment points laterally, and it is only by bringing the distal end of the neck into a horizontal position that accurate apposition of the fragments can be made. Not only are the fragments brought into apposition by full abduction of the leg, but the tension on the capsule provides for direct mutual pressure of the fractured surfaces. The trochanter being in contact with the pelvis, any muscular effort likely to displace the fragment is impotent, and fixation is complete.

If absorption of the neck and shortening and stiffening in the movements of the hip result after the abduction treatment, the tilt downwards of the pelvis on the affected side, in order to bring the two legs parallel for locomotion, will correct the shortening. If adduction follows treatment of an injury to the hip, the reverse is, of course, the case. The abduction treatment is now the standardised routine. To encourage us further, Whitman points out that the fracture in the aged is usually at the base of the neck, and that the central fracture is more common in the young and the vigorous. The reverse of what was formerly believed. Bearing this in mind, and also that fractures elsewhere unite readily in aged subjects, we have every ground for optimism when considering the prognosis of these cases.

It may be confidently predicted that the immediate and efficient treatment of fractures of the neck of the femur by the abduction method will be followed, in most instances, by repair. If union fails when accurate apposition of the fractured surfaces has been maintained for a sufficient time—as confirmed by X ray examinations—it indicates a low vitality in the tissues, and Whitman advises in such cases a reconstruction operation which will be mentioned later.

In 1905 [1] I designed an apparatus for the reduction of fractures of the lower extremity which resisted manual traction, and in the absence of one of the more perfect tables of the Hawley type, I still find it useful. The original cost was £2 10*s*. (Fig. 1.)

The apparatus consists simply of two iron gates, about 4½ ft. long, swung on an upright which carries a perineal bar, attached to which is a small support for the sacrum of the patient which is included in the plaster, but afterwards removed. This pelvic support and the upright on which it sits are supported by a heavy stand. On the distal ends of the gates are rollers, square on section, in order to obtain a firm hold on the cords or bandages when extension is being applied. By pushing the handle inwards the square bar fits into a hole of the same shape and diameter, and so locks. This is a simple substitute for a ratchet Fixed to the stand, and running at right angles to it along the floor between the two gates, is a bar, and the distance of the gates from this bar indicates the exact amount of abduction and enables plaster to be applied with both legs spread from the pelvis at equal angles. In this way there can be no obliquity of the pelvis. If it is desired to note the exact amount of extension required to hold the fracture reduced two Salter's sportsmen's balances, registering at least 50 lb., are necessary additions.

I have found the apparatus useful in all recent cases of fractured femur in any position where shortening could not be reduced with ease, and in the treatment of malunited fractures. It provides a substitute for the block-and-tackle pulley arrangement as a means of reducing the overlapping and shortening in the latter group, and it facilitates the application of plaster of Paris when employed during the treatment (Fig. 2).

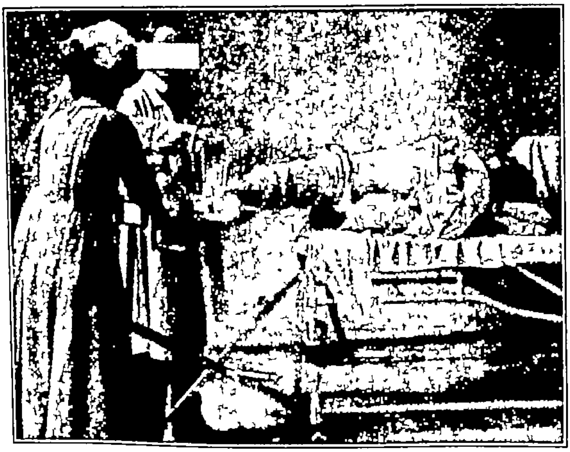
Reduction of an Intracapsular Fracture of the Neck of the Femur.

The patient is anæsthetised The gates are brought to the end of the table, and the patient is put astride the padded perineal crutch Manual traction and manipulation is usually sufficient for reduction, but by attaching the foot to the end of the gate, extension and abduction are readily obtained, and the application of the plaster of Paris rendered very simple

It is best to apply the plaster to the foot and lower third of the leg in the first instance, and when this has set a clove-hitch or a wet skein of wool, passed round the ankle and over the foot in figure-of-eight fashion—as recommended by Watson Cheyne—is connected with the ratchet. These connexions may be incorporated in the plaster bandages used to complete the cast before the extension is released. Or, alternatively, a steel pin is passed beneath the tendo Achillis in contact with the os calcis to act as a connecting link between the foot and the ratchet. The steel pin is removed when the plaster coat is complete.

The limb on the sound side is held abducted to the normal limit by an assistant who stands at the end of the gate, or it may be attached to the rachet by a clove-hitch. The surgeon notes the normal range of abduction on the uninjured side. The knee and the thigh are kept slightly flexed by a sling under the knee from the upright bar which is attached to the gate. This flexion corrects the inversion of the foot. The injured leg is extended by tightening the ratchet, slowly abducted by moving the gate, and rotated inwards with the hands. The surgeon or an assistant supports the joint and presses the trochanter gently downwards. The neck of the bone is first felt to hitch on the upper border of the acetabulum, but this obstacle is easily overcome. Abduction is continued until the normal range is obtained. The trochanter rests against the side of the ilium, and the anatomical relationship between the shaft and the neck of the femur is now restored. The limb is in the Whitman attitude of extension, complete abduction, and slight inward rotation. Plaster of Paris is rolled on with great facility, with the aid of this apparatus. The plaster is allowed to dry with the patient still in position on the gates. (Fig 3.)

FIG. 3.



Application of plaster of Paris for fractured hip

In the ward the head of the bed is raised one or two feet, an inclination the reverse of that required for traction. It is more comfortable, and Whitman thinks that the influence of this position on the blood-supply makes the chances of repair more favourable

The completed spica (Fig 4) is retained in position for from 8 to 12 weeks, and several more weeks are spent in bed for treatment with massage and the restoration of movements in the joints. Weight-bearing is not permitted until the movements of the joints are free and painless, and X ray photographs indicate the stability of repair.

Jones treats these cases on his abduction frame slightly modified. In very feeble patients who are bad surgical risks, a Thomas splint slung out over the side of the bed is substituted, the sound leg being kept in abduction by sandbags.

Waldenstroem [2] says there is a marked difference between the results obtained when the fracture is held by a plaster cast and when it is held by extension. When a plaster cast is used, out of 15 cases 11 gave good results, 8 with bony union. In 18 cases treated by extension methods there were three good results. Bony union resulted in two.

The treatment of fractures of the neck of the femur may be summarised as follows:—

1. In all subjects, of whatever age, reposition of the fragments should be attempted, unless the patient is too frail for treatment, and then the fracture must be neglected. Sometimes, but not often, such a patient can endure walking on a calliper splint, but in the majority the rest of their lives will be spent either in bed or in a chair.

---

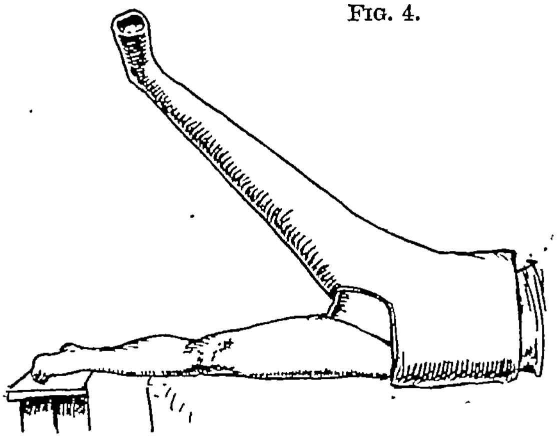
[1] Medical Press and Circular, March 8th, 1905

[2] Jour. de Chir., 1924.

2. When the fracture is reduced under anæsthesia, a plaster-of-Paris splint, as described by Whitman, is the most effective appliance.

3. To apply a plaster case properly for this fracture, some form of orthopædic table is most desirable, but a perineal prop with pelvic support which clamps on to any table, gives immeasurable help.

Fig. 4.



Completed plaster case (after Whitman).

4. In the absence of a perineal prop, counter-fixation of the pelvis during reduction is accomplished by passing a strong bandage round the groin on the sound side, and tying it to the table near the patient's head.

5. In cases unsuitable for plaster, good abduction and extension can be maintained on Jones's frame, or the injured limb may be slung in a Thomas splint in abduction over the side of the bed, and tilting of the pelvis prevented by supporting the sound leg in abduction with sandbags.

6. The position of abduction should be maintained for at least two months.

Two recent cases illustrate the above remarks.

A woman, aged 79, was knocked down by a bicycle in 1923. She was treated by the abduction method after reduction under an anæsthetic. She has firm bony union, there is no shortening, and no loss of movements in the hip-joint. In January last I wrote asking her to report. She replied as follows in February: "My injured hip is as well as ever. I have no lameness, do not use a stick or crutches, I have no pain or limp, and have full movements."

A man, aged 70, was admitted in 1923. He was feeble and difficult to manage, and was treated by a Thomas splint slung in abduction over the side of the bed in extension; he was under supervision for three months in hospital. He reported three weeks ago, walking on crutches, with slight crutch palsy. He would not wear a calliper splint; 1¾ in. shortening. Full movements of flexion and extension; strong fibrous union. With a little encouragement he discarded the crutches, but walks with a marked limp.

In this case no anæsthetic could be given, and there was no attempt at orthodox reduction. An X ray plate showed clearly an atheromatous artery in the pelvis, which is an indication of the senility of this patient, although nine years younger than the case referred to above.

Whitman's Reconstruction Of Whitman has
designed a reconstruction op old-
cases, where absorption of th
and where the functional resu
that this operation is to be pre
The operation is designed to restore early capacity in vigorous subjects. The base of the trochanter is cut through in an oblique direction with a chisel, the obliquity corresponding to the angle of the neck. A new neck is thus formed, and is thrust into the acetabulum with the leg in abduction. The trochanter is drawn downwards and is secured by a peg to the femur at a lower level.[4]

Fracture of the Trochanters.

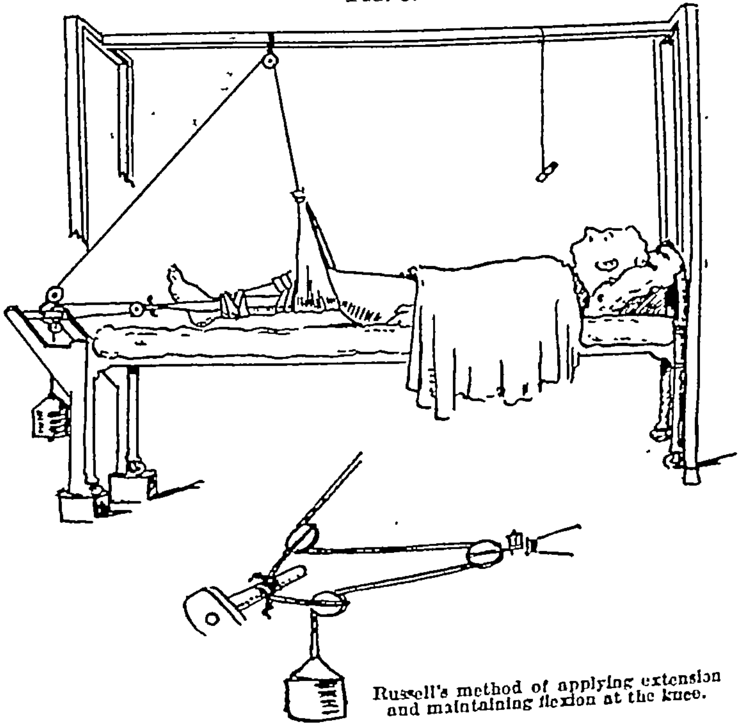
In subjects under 18 years, epiphyseal separation of the great trochanter is not uncommon. Fracture of the great trochanter is rare. When it occurs the trochanter is displaced upwards, and the best apposition can be obtained by the abduction method of treatment.

Langdon[5] reports two cases of fracture of the lesser trochanter. Only 25 are recorded in the literature. Langdon's cases were those of boys 12 and 16 years of age. The cause is said to be a sudden strain on the ilio-psoas muscle, causing avulsion. The pathognomonic sign is inability to flex the injured limb in the sitting position. Poston[6] also calls attention to this injury, in a boy aged 14. The treatment in the early cases was very variable, but notwithstanding the difficulty of getting accurate apposition and reduction, the results were uniformly satisfactory. Operations are therefore contra-indicated. In Poston's case a plaster spica with the thigh flexed at the hip was applied for 14 days, and afterwards treatment was carried on by massage and passive movements. He had full recovery in 36 days.

Fractures of the Shaft of the Femur.

General Considerations.—Seventy-five per cent. of the fractures of the femur seen at the Mayo Clinic present mal-union, non-union, delayed union, chronic osteomyelitis, or joint stiffening following treatment elsewhere. This is the statement of Meyerding in the "Mayo Clinics" of 1923, and it is a severe

Fig. 5.



Russell's method of applying extension and maintaining flexion at the knee.

---

[4] A complete description of the operation appeared in Surgery, Gynecology, and Obstetrics, June, 1921.

[5] Surg., Gyn., and Obs., Abs., October, 1924.

[6] Brit. Jour. of Surg., October, 1921.

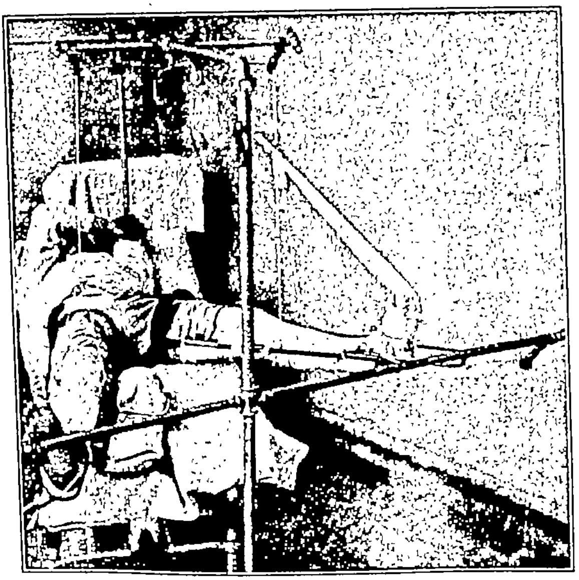
commentary on the treatment of recent fractures elsewhere.

To obtain satisfactory results in fractures of the shaft there are two alternatives open to those surgeons who prefer non-operative methods:—

(a) The shortening and deformity may be reduced under an anæsthetic at once by means of powerful traction, if necessary, on a suitable orthopædic table. The limb—including the foot and the lower part of the body—is then encased in carefully applied plaster of Paris. (I do not practise this method apart from cases of fractured hip.)

(b) The deformity may be reduced under an anæsthetic, with the knowledge that the reduction will, in most cases, not be maintained completely by any form of splint, but will be gradually restored under the influence of traction and simple contrivances to correct lateral or antero-posterior deviations.

FIG. 6.



Fracture of the femur (upper third). Patient in bed after reduction. Note gauze glued to sole of foot to support it at right angles.

The methods of treatment are much the same, whatever the position of the fracture. When the fracture is in the trochanteric region, it is necessary to remember that the upper fragment is usually abducted, the lower fragment drawn upwards and inwards. Occasionally, when the obliquity runs from above downwards and inwards, the upper fragment may be pushed inwards instead of outwards. It is best to treat these high fractures in abduction, although it is doubtful if the upper fragment remains abducted once the limb is placed in a position of comfortable extension. Notwithstanding this, I think abduction is the best position on the principle of "safety first"—for if union takes place with the lower fragment adducted the functional result is unsatisfactory, owing to the necessity of compensatory raising of the pelvis on the injured side.

Mr. Russell[1] holds that there is only one circumstance which can justify operation in recent fractures of the shaft; that is, mechanical impediment to the reposition of the fragments; this is a sound doctrine.

I would like to say here that in simple fractures of the shaft of the femur, or of any other long bone, it must be an extremely difficult matter for soft structures to impose themselves between the fragments if sufficient extension is applied. All the muscles and other tissues run, for the most part, in a parallel line to the long axis of the bone, and the more they are pulled upon the more there is a tendency to disengage themselves from the line of fracture. When the patient is out of the anæsthetic, muscular tone comes into play, as if there were bands of elastic reaching from the pelvis to the tibia and fibula, and in fracture of the long bones tonic shortening of the muscle will be progressive.

"Our first aim, then," says Mr. Russell, "will be to pull out these muscles to their correct length, and when we have accomplished this we may be sure that every other structure of the thigh will be in its correct position, including the fragments. This does not mean exact anatomical reposition, which is neither necessary nor even, in my opinion, always desirable." This is another fundamental truth, for everyone with experience of the treatment of fractures knows that a slight lateral or antero-posterior displacement of fragments is of no account, provided there is no abnormal angulation or rotation.

There are many observations in Mr. Russell's paper worthy of note. "What must we pull upon?" he says; "clearly the tibia and fibula, seeing the muscles are attached to them. We are going to use strapping and bandages for the extension, and we shall, accordingly, not carry them above the knee for reasons that are obvious. I think that the practice, which seems universal, of carrying the strapping up the thigh indicates some confusion in our mental picture of the object to be attained. Anxiety as regards the ligaments of the knee is quite needless, for, being attached to a fragment, they cannot be subject to stretching. The whole of the extending force will fall on the muscles, none at all on the ligaments. To convince ourselves of this, we only have to reflect that if the muscles were severed at the seat of fracture the limb would drop off." Mr. Russell might have gone further and said that if the ligaments of the knee were pulled upon and loosened after partial union, they very quickly took up the slack during convalescence. (Fig. 5.)

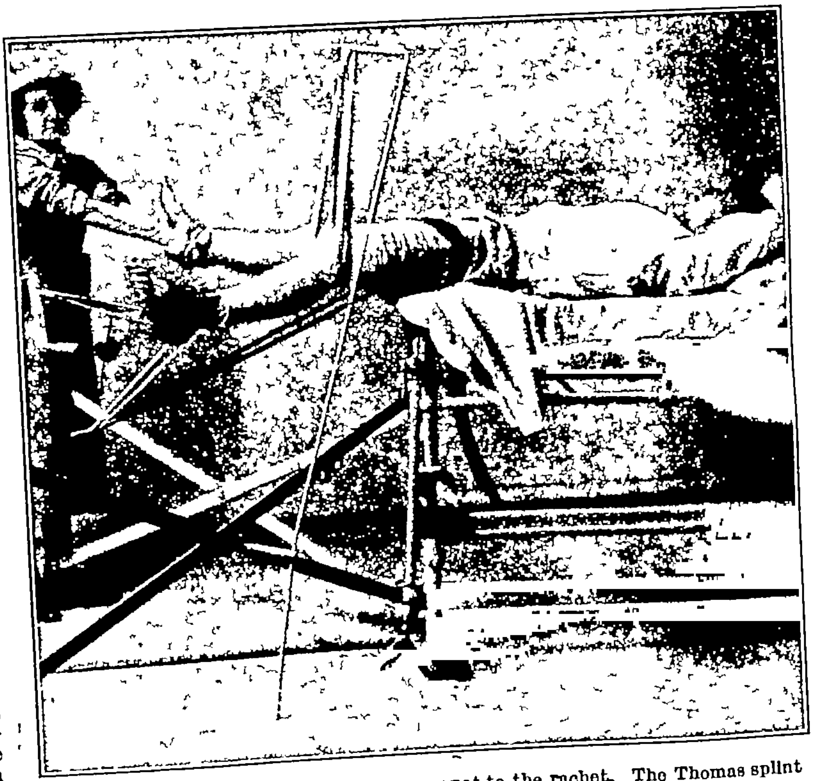
In high-up fractures of the shaft the upper fragment is usually flexed and abducted; the lower fragment is drawn up and adducted. A long-axis pull will correct the shortening, and simultaneously with the pull the limb must be brought into abduction to get proper alignment. These fractures do well in a Thomas splint slung by pulleys to a Balkan frame, with either fixed extension, as recommended by Jones, or a 10 to 15 lb. weight-and-pulley extension attached to the end of the Thomas splint (Fig. 6). The sound leg is kept in slight abduction with sandbags (or slung in a Thomas splint) to prevent tilting of the pelvis, and the foot of the bed should be raised. The foot should be maintained straight, as the temporary rotation outwards of the upper fragment need not be considered.

---

[1] Brit. Jour. of Surg., January, 1924.

We must not think too seriously about the displacement of fragments of the shaft by muscular action. It was pointed out by Lucas-Championnière, more recently by Sir Robert Jones, and again by Mr. Russell, that the displacement caused by muscular spasm is only a transient phenomenon tending to disappear when the fracture is reduced and the limb placed in a comfortable position free from pain, but if shortening is not reduced and the extension apparatus is inefficient, progressive contraction of the muscles is to be expected. The temporary nature of muscle spasm is particularly noticeable in fractures of the lower third. Much attention is drawn to the fact that the lower fragment is displaced backwards by the gastrocnemius muscle in dangerous relationship to the popliteal vessels. It is taught that these muscles must be relaxed in the treatment of such fractures, but numbers of surgeons, including myself, reduce them with strong extension without any misgivings whatever. The action of gravity or the tendency to fall backwards, obliterating the natural convexity forwards of the femur, with perhaps resultant genu recurvatum, is easily countered by a sling behind the point of fracture. So much attention has been paid to this in my own cases that many times I have obtained a slight increase of the natural bowing of the femur forwards, but without any undesirable after-effects as regards function.

Fig. 7.



Powerful extension can be applied from a spat to the rachet. The Thomas splint is then fixed in position, the tapes tied, and the spat removed.

We should remember that comfort is an essential in the treatment of a fracture. Spasms and counter-spasms occur in the search for relief and the muscles are never at rest, the fragments are disturbed and displacements result.

Treatment of Fracture of the Upper Third of the Shaft.

If the shortening can be reduced by manual extension and abduction under anæsthesia, a Thomas splint is applied and the extension tapes secured to the end of the splint while traction is maintained. If there is difficulty in overcoming the shortening at the first try, it is probable that with sufficient and continuous extension the proper length will be obtained within the first week. The Thomas splint is slung over the side of the bed on a Balkan frame in a position of abduction with the sound leg slung or ported by sandbags. (Fig. 6.) In some cases reliance ll be placed on fixed extension—i.e., tightening up tapes frequently as the muscles relax, in others weight-and-pulley attachment is fastened to the d of the splint. If the strapping tends to slip during the first 10 to 14 days, an assistant grasps the ankle and extends while new strapping is applied. I have had no trouble in obtaining union without shortening by these simple means.

Fractures of the Middle of the Shaft.

There should be no difficulty in the treatment of these cases with a Thomas splint, slightly bent at the level of the knee. The shortening is reduced, or as nearly reduced as possible, under anæsthesia, and fixed extension is rigidly maintained to the end of the Thomas by means of the orthodox strapping and tapes (Fig. 7). It is in this position that the action of gravity, causing sagging backward of the fragments and bowing of the femur, must be countered. In rare cases shortening may still persist at the end of a week, and powerful stretching with pulleys or special appliances may be required. To prevent bowing backwards, a tight strip of bandage is clipped to the bars of the Thomas splint directly behind the fracture point; nothing more is necessary, but this band throughout the treatment must be kept tight. If an X ray photograph shows some lateral deviation of fragments, a pull may be exerted from one bar to the other by a loop of bandage round the limb, above or below the fractured bone according to the amount of displacement. Some Thomas's splints are fitted with lateral pressure pads adjusted by a screw arrangement attached to the bars by means of which lateral deviations can be controlled.

Sir Robert Jones recommends that for further control a gutter-shaped sheet metal splint, extending from the buttock fold to the lower third of the leg with a good wool pad in the hollow of the knee, should be applied. Another grooved splint on the front of the thigh, stopping short above the patella, gives further support. Instead of fixed traction, in certain cases it may be more convenient to apply a weight and pulley of from 15 lb. to 20 lb. attached to the end of the splint.

Fractures of the Lower Third of the Shaft.

The interest in connexion with the treatment of these fractures is owing to the displacement of the lower fragment backwards as a result of the spasm of the gastrocnemii muscles. The upper fragment is usually adducted.

Again it must be pointed out that muscular spasm is only transitory, and Sir Robert Jones quotes an interesting case of compound fracture in which the limb was put in comfortable straight extension, and the spasm was actually seen to pass off with the gradual disappearance of the flexion deformity of the lower fragment. Nevertheless, when the shortening has been reduced under an anæsthetic, by full extension, the Thomas splint should be bent to half a right angle at the knee before the tapes are secured at the end. A strip of bandage is kept tightly applied under the lower fragment to ensure gradual restoration of alignment. If backward displacement persists, which is unlikely, division of the tendo Achillis is indicated. When reducing the fracture I do not believe there is any real danger in applying full extension without flexing the knee (Fig. 7).

Fracture of the Shaft of the Femur in Children.

I have most experience in the oblique or spiral fractures of the shaft in children, and I was surprised to find in how many cases it was difficult to maintain a good reduction of the fragments. Whatever methods were employed, immediate X ray photographs showed a disappointing result; the final result was all that could be desired.

The Bryant suspension frame is not satisfactory in children over the age of 6 years, as the weight of the body tends to tear off the extension straps and frequent reapplication is necessary. When used in young children more traction will be obtained when only one limb is suspended, but the patient is more uncomfortable and the nursing is more difficult.

In a large series of cases described by Burdick and Siris [*] the favourite method was a plaster spica and traction—118 cases treated Bryant's frame and suspension was next in popularity—90 treated. Fourteen were treated with a Thomas splint and traction, and two with a Hodgen splint and traction. It was necessary in a few cases to resort to operation.

In my early days I operated on these cases, but subsequent experience showed that in the case of children an apparently bad primary result was followed by an extremely good final result, and X ray photographs taken a year or two afterwards barely indicated the line of the original injury. Not infrequently a child who was discharged from hospital with shortening ultimately presented itself with slight lengthening of the injured limb. In children, more than in others, it is necessary to emphasise the fact that perfect anatomical reduction is not essential for perfect functional recovery. There appears to be a stimulation of the growth of bone in its longitudinal direction, irrespective of the location of the fracture in the shaft.

One of the best methods of treatment is to place the child across a perineal prop, reduce the shortening, apply plaster strapping for subsequent extension, and over this a plaster spica from the malleoli to the ribs with the limb in moderate abduction. A weight-and-pulley extension of 10–15 lb. is employed. The plaster is removed in about six weeks. The continuous skin traction is used not so much to reduce shortening but to try and prevent any change in the relative position of the fragments. In children under 6 years of age extension of the leg in a vertical position to a horizontal bar over the bed is better than the method just described A small Thomas splint—even small enough to fit a new-born child suffering from obstetrical fracture—also gives good results. A simpler method in infants is to bind the thigh and the extended leg to the front of the abdomen with a bandage. In the process of growth faulty alignment becomes corrected. Union is very rapid in these cases, and all fixation methods may be abandoned in less than three weeks.

A boy, aged 11, was admitted to hospital in 1921 with a transverse fracture of the humerus and a transverse fracture of the femur. Perfect alignment was obtained in the first instance with ease, by means of a Thomas splint, but later lateral displacement of the fragments occurred with ¼ in. shortening. The mother wrote to me in January, 1925, as follows: "He has had no trouble of any kind from it, and now plays football at school. There is no shortening or defect."

This is another illustration showing how absolute anatomical position is not necessary for perfect function; and displacements, when the alignment is correct, may be ignored even more so in children than in adults.

QUANTITATIVE DATA IN TISSUE REACTIONS TO ULTRA-VIOLET RADIATIONS.[*]

BY P. R. PEACOCK, M.R.C.S. ENG.,
VAUGHAN MORGAN SCHOLAR AND MARGARET BUTCHER SCHOLAR, MIDDLESEX HOSPITAL.

ON the purely physical side, the subject of ultra-violet radiation has been very thoroughly investigated, and a logical explanation is available for the behaviour of many inert substances under the influence of the rays. The same cannot be said of the physiological and therapeutic aspects of the subject, for, although certain striking effects are produced on living organisms as a result of exposure to the rays, there are still many processes of whose mechanism we have no exact knowledge.

It is well known, for example, that exposure to the rays frequently results in bronzing of the skin, due to increase of melanin granules in the basal cells of the epidermis. This fact has been associated with a coincident improvement of bodily fitness, and advantage has been taken of it in heliotherapy. At the same time, it is generally admitted by those who have studied a great number of cases that there are unaccountable variations in the response of different individuals to the action of the rays. Some patients pigment well and benefit greatly by treatment; some merely freckle and may not do so well; others again pigment not at all or only slightly, deriving but little benefit from the treatment, though this is by no means invariably true.

If investigation is carried out with a pure beam of ultra-violet rays, instead of employing the full solar spectrum, certain effects are rendered striking which would otherwise be masked.

Fluorescence Under Ultra-violet Rays.

Dr. Mottram and Prof. Russ [1] described in 1920, before this society, the curious appearances seen when objects are examined in a beam of rays from which the visible wave-lengths have been filtered off by means of Wood's glass. The following is a brief quotation from their paper:—

> "The skin presents a generalised violet fluorescence, but, over the face and, to a less extent, over the rest of the body, dark non-fluorescent spots are seen, numerous in some individuals, almost absent in others. Freckled persons are usually thickly spotted, but, on the other hand, perfectly clear complexions may present a similar appearance. There are also to be seen, especially on the face, minute brightly fluorescent spots, having the appearance of stars."

Examination, in this way, of different skins under the ultra-violet beam revealed the fact that fair skins fluoresce more brightly than dark, and that the skins of dark races do not show a general fluorescence, but only over certain special regions. (The same applies to areas of artificially increased pigmentation, such areas being no longer as brightly fluorescent as before.) Thus, the same brightly fluorescent spots are to be seen on the face as in fair races, and the palms of the hands also present a fair degree of fluorescence.

Examination of the skin structures and derivatives shows that they may be divided into two groups—fluorescent and non-fluorescent.

[*] Annals of Surgery, June, 1923.

[*] Read before the Section of Electro-Therapeutics of the Royal Society of Medicine, April 17th, 1925.

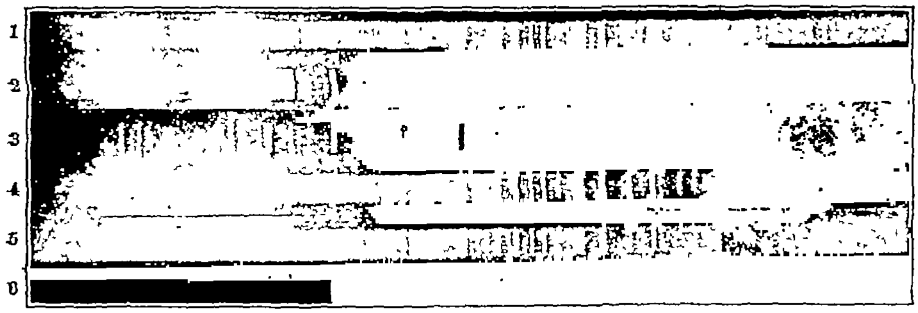
[1] Mottram, J. C., and Russ, S.: Proc. Roy. Soc. Med., 1920, vol. xiii. (Section of Electro-Therapeutics), pp. 143–145.

The *fluorescent structures* are the following: (1) The keratinised layer of the epidermis; (2) the nails (or non-pigmented claws in animals); (3) white hair (or white fur in animals); and (4) the cornea and lens (derived from skin structures). Of the skin secretions, the sebum, the cerumen, and the vernix caseosa of new-born infants. Milk is also fluorescent.

The *non-fluorescent structures* are: (1) The pigment and pigmented epidermis; (2) pigmented claws (in animals); and (3) pigmented hair (or fur in animals). Of the secretions, the sweat is non-fluorescent. The blood is also non-fluorescent.

Of the above-mentioned constituents of the skin the sebum is the most brilliantly fluorescent, and its presence in the sebaceous glands probably accounts for the brilliant spots seen in the ultra-violet beam. Melanin in a state of purity and all melanotic tissues examined are completely non-fluorescent. Both melanin and sebum prove, on spectrum analysis, to be powerfully absorbent of the ultra-violet rays. When a body is said to fluoresce in a beam of pure ultra-violet, it means that a certain amount of the incident invisible beam is being converted into rays of longer and visible wave-length, and that the intensity of ultra-violet is reduced by this amount at least.

FIG. 1.



Absorption spectra, mercury-vapour lamp: 1. Unscreened. 2. Vaseline screened. 3. Lanoline screened. 4. Lard screened. 5. Empty cell. 6. Wood's glass, plus vaseline screen.

Fluorescence a Protective Phenomenon.

Fluorescence must, then, from the ultra-violet point of view, be a protective phenomenon. The following experiments were performed to substantiate this.

From a number of substances examined, three were selected: lard, lanoline, and vaseline (yellow). Lard is non-fluorescent. Lanoline fluoresces very like human sebum. Vaseline fluoresces very brilliantly. Absorption spectra were taken through 0·1 mm. thickness of each of these substances (Fig. 1).

It will be seen from these spectra that lard does not absorb the rays at all. Lanoline absorbs wave-lengths shorter than 2900 Å.U. Vaseline absorbs the whole ultra-violet spectrum, with the exception of the small band of wave-lengths from 3800–3050 Å.U.

The skin of the forearm was then examined by ultra-violet and an area of even fluorescence was selected. This area was covered by a perforated shield by means of which a series of small areas could be exposed to the rays. Over one area lard was smeared; over a second, lanoline; and over a third, vaseline. Two similar untreated areas were used as controls.

The arm was then fixed in position, 15 cm. from the centre of a Cowper-Hewitt mercury-vapour lamp, consuming 203 watts, and all areas were exposed simultaneously for five minutes. In one hour from the end of exposure erythema had developed over all areas except that smeared with vaseline. The vaselined area showed no sign of reaction, though the other areas developed pigmentation within a week, [illegible] marked in the control areas and in that smeared with lard. The method of smearing the skin was in each case to apply a small trace of the substance to the area and rub it in gently, removing all excess by wiping dry with a clean towel.

Following this experiment, the protective power of vaseline was further investigated on similar lines. It was found that skin treated in this way by smearing with yellow vaseline is capable of standing three and a half times the length of exposure necessary to produce the same degree of erythema on normal skin. White vaseline is less protective than yellow, and shows less absorption spectrographically.

Skin Reactions in Relation to Intensity of Radiation.

The next series of experiments was undertaken with the object of seeing whether skin reactions run pari passu with physical measurements of the intensity.

The intensity of radiation from the mercury-vapour lamp is determined by the power consumption expressed in watts (obtained by the product of the current in amps. flowing through the lamp and the potential difference in volts between its terminals). When the power remains constant dosage depends on the time of exposure and the distance of the patient or object from the lamp.

Measurements of variation of the intensity of radiation with distance were made with a Furstenau (selenium) intensimeter, the power consumption of the lamp being kept constant at 300 watts. In this way the points on the full line curve in Fig. 2 were obtained. The thin dotted curves show the ordinary inverse and inverse square law curves, and it will be seen that, owing to the size of the lamp, the actual variation is not so rapid as from a point source.

Experiments were next made by exposing portions of normal human skin to the radiation at different distances ranging from 20 to 100 cm. The time of exposure for each distance was calculated from the data just mentioned, so that each corresponded to 1·5 E. (1 E = exposure at 30 cm. distance for two minutes with lamp consuming 310 watts and results in slight erythema in two hours and slight pigmentation in one week.)

The main result of these observations, given in detail in the table, was that, within the limits of error of observation, the skin reactions were identical until the intensity was reduced to about 8 per cent., provided the time of exposure was correspondingly prolonged. Beyond this the effect was slightly less marked. The exposures were, of course, made on the same individual.

Table Showing Results of Detailed Observations.

Intensity (per cent.).	Watts.	Time.	Distance in cms.	Dose.	Erythema.	Pigmentation.
100	451	1′	20	1·5 E	+ + +	+ + +
67	,,	1′ 30″	30	,,	,,	,,
43	,,	2′ 10″	40	,,	,,	,,
27·8	,,	3′ 30″	50	,,	,,	,,
18	,,	5′ 37″	60	,,	,,	,,
12·3	,,	8′ 11″	70	,,	,,	,,
10	,,	10′	80	,,	,,	,,
7·3	,,	13′ 45″	90	,,	+ +	+ +
6·7	,,	15′	100	,,	,,	,,

1 E results in + + erythema in 24 hours and + + pigmentation in one week.

An attempt was made to obtain a direct skin reaction with rays of a particular wave-length by employing filters. A combination of Wood's glass and a vaseline cell showing spectroscopically absorption of all wave-lengths but a short band from 3800–3650 Å.U. was used (Fig. 1, No. 6). With this filter it was necessary to give 20 times the control exposure in order to get a faint transient erythema. It is possible that, in spite of the spectrographic evidence of the predominance of line 3650 Å.U., some shorter wave-length rays may have penetrated the screen and caused this effect.

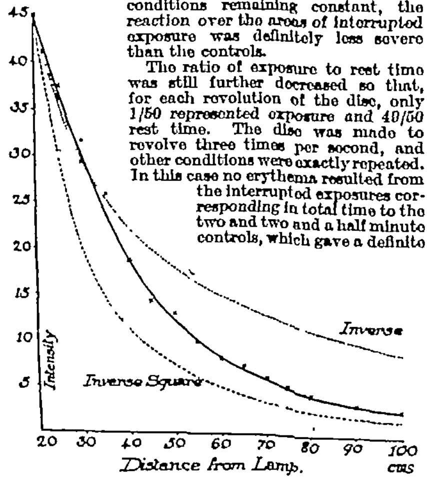
Cumulative Effect of Repeated Small Doses.

The next thing investigated was the cumulative effect of repeated small doses. The method of investigation was to interpose a revolving disc between the source of radiation and the skin under examination. By variation of an aperture in the disc, different ratios of "exposure" to "rest" interval can be obtained and the frequency of exposure varied by the rate of revolution of the disc.

It was found that, with a ratio of exposure to rest interval of 1 to 1 a purely cumulative effect is produced. With 1/10 exposure to 9/10 rest, when the revolutions were increased to three per second, other conditions remaining constant, the reaction over the areas of interrupted exposure was definitely less severe than the controls.

The ratio of exposure to rest time was still further decreased so that, for each revolution of the disc, only 1/50 represented exposure and 49/50 rest time. The disc was made to revolve three times per second, and other conditions were exactly repeated. In this case no erythema resulted from the interrupted exposures corresponding in total time to the two and two and a half minute controls, which gave a definite erythema within a few hours. The interrupted exposure corresponding to the three-minute control showed an erythema corresponding to the two-minute control. A further interrupted exposure of total time equal to a control of three and a half minutes resulted in an erythema corresponding to that of the two and a half minute control.

FIG. 2.



Thus it appears that, for the shorter exposures (two and two and a half minutes total time) a ratio of "exposure" to "rest" time of 1 to 50 does not result in a cumulative effect as far as erythema reaction and subsequent pigmentation is concerned; but the tissues have had the same actual exposure to the rays as would result in a definite burn if given as a continuous exposure. A continuation of observations with still further reduction of the momentary exposures is being made, but the times of exposure are necessarily very prolonged. Perthes[2] has shown that, when two doses of U.V. radiation are given to the skin with a long time-interval between them, less reaction is produced than if the whole dose is given at one time.

The possibility of a constitutional effect of repeated exposure of rats to ultra-violet rays was investigated on the following lines:—

A group of 40 animals of similar age, size, weight, and colour was selected and divided into two subgroups, 20 for experiment (Group I.) and the remaining 20 for control examination (Group II.). The males and females were segregated in each instance. The hair over the backs of the Group I. animals was cut short so as to obviate the dissipation of ultra-violet rays by fluorescence or heat production in the hair. These animals were exposed to the full radiation from the mercury-vapour lamp for five minutes daily at 50 cm. distance for 30 days. The power consumption of the lamp was 180 watts, giving a daily dose of ¼ E and a total dose of 7·5 E.

The animals in both Groups I. and II. received similar food and were housed under the same conditions as regards temperature, &c. Bi-weekly weight measurements show about 10 per cent. slower rate of growth in Group I. animals. At the end of one month the exposures were stopped, and one week later all the animals of both groups were inoculated with Jensen's rat sarcoma (J.R.S.) on the right side and with slow sarcoma on the left. Tumour measurements over a period of six weeks showed no appreciable difference between Groups I. and II. Thus it appears that, within the limits of the experiment, there was no constitutional effect calculated either to resist or favour tumour growth. A second series on similar lines gave the same result.

An attempt was made to find the lethal dose of ultra-violet rays for J.R.S. in vitro.

In view of the rapid absorption of the rays by the tissue, the sections of tumour must be very thin. To obtain a sufficiently thin uniform section to allow the rays to penetrate effectively, two razor blades were soldered to a metal handle so that the cutting edges were 0·5 mm. apart. With this double razor, sections were cut from actively growing tumours, care being taken to avoid any necrotic areas. The sections were laid flat, and, with due aseptic precautions, were treated as follows:—

Sections (*a*) were exposed to the full radiation from the mercury-vapour lamp.

Sections (*b*) were screened by 1·5 mm. of glass, to exclude the majority of the U.V. rays.

Sections (*c*) were set aside during the exposure and were used as controls.

A range of doses from 0·6 to 6 E was employed, the material being subsequently inoculated into batches of animals. When 6 E was reached all the (*a*) *inoculations either failed to grow at all or grew* small tumours for about ten days and then disappeared (0 per cent. growth). The (*b*) inoculations showed 33⅓ per cent. of growth, while the controls (*c*) gave 66⅔ per cent. growth. The lesser doses of U.V. rays allowed some growth in an appreciable number of cases, but 6 E was found to correspond to the lethal dose.

Conclusions.

From the foregoing experiments, it is, I think, possible to draw certain conclusions.

1. Since the skin surface is rendered visible by fluorescence, when only the invisible ultra-violet rays fall upon it, it is obvious that a greater or less amount of the incident rays is being dissipated at the skin surface as light and is consequently incapable of acting on any deeper structures.

2. Since fluorescence commences directly the skin is exposed to ultra-violet rays, whereas pigmentation only occurs as a result of considerable exposure, it is logical to suppose that, in fluorescence, we have a more immediate protection from excessive radiation, as far as ultra-violet is concerned, than in pigmentation.

Fluorescence a Protective Phenomenon.

Fluorescence must, then, from the ultra-violet point of view, be a protective phenomenon. The following experiments were performed to substantiate this.

From a number of substances examined, three were selected: lard, lanoline, and vaseline (yellow). Lard is non-fluorescent. Lanoline fluoresces very like human sebum. Vaseline fluoresces very brilliantly. Absorption spectra were taken through 0·1 mm. thickness of each of these substances (Fig. 1).

It will be seen from these spectra that lard does not absorb the rays at all. Lanoline absorbs wave-lengths shorter than 2900 Å.U. Vaseline absorbs the whole ultra-violet spectrum, with the exception of the small band of wave-lengths from 3800–3650 Å.U.

The skin of the forearm was then examined by ultra-violet and an area of even fluorescence was selected. This area was covered by a perforated shield by means of which a series of small areas could be exposed to the rays. Over one area lard was smeared; over a second, lanoline; and over a third, vaseline. Two similar untreated areas were used as controls.

The arm was then fixed in position, 15 cm. from the centre of a Cowper-Hewitt mercury-vapour lamp, consuming 203 watts, and all areas were exposed simultaneously for five minutes. In one hour from the end of exposure erythema had developed over all areas except that smeared with vaseline. The vaselined area showed no sign of reaction, though the other areas developed pigmentation within a week, most marked in the control areas and in that smeared with lard. The method of smearing the skin was in each case to apply a small trace of the substance to the area and rub it in gently, removing all excess by wiping dry with a clean towel.

Following this experiment, the protective power of vaseline was further investigated on similar lines. It was found that skin treated in this way by smearing with yellow vaseline is capable of standing three and a half times the length of exposure necessary to produce the same degree of erythema on normal skin. White vaseline is less protective than yellow, and shows less absorption spectrographically.

Skin Reactions in Relation to Intensity of Radiation.

The next series of experiments was undertaken with the object of seeing whether skin reactions run pari passu with physical measurements of the intensity.

The intensity of radiation from the mercury-vapour lamp is determined by the power consumption expressed in watts (obtained by the product of the current in amps. flowing through the lamp and the potential difference in volts between its terminals). When the power remains constant dosage depends on the time of exposure and the distance of the patient or object from the lamp.

Measurements of variation of the intensity of radiation with distance were made with a Furstenau (selenium) intensimeter, the power consumption of the lamp being kept constant at 300 watts. In this way the points on the full line curve in Fig. 2 were obtained. The thin dotted curves show the ordinary inverse and inverse square law curves, and it will be seen that, owing to the size of the lamp, the actual variation is not so rapid as from a point source.

Experiments were next made by exposing portions of normal human skin to the radiation at different distances ranging from 20 to 100 cm. The time of exposure for each distance was calculated from the data just mentioned, so that each corresponded to 1·5 E. (1 E = exposure at 30 cm. distance for two minutes with lamp consuming 310 watts and results in slight erythema in two hours and slight pigmentation in one week.)

The main result of these observations, given in detail in the table, was that, within the limits of error of observation, the skin reactions were identical until the intensity was reduced to about 8 per cent., provided the time of exposure was correspondingly prolonged. Beyond this the effect was slightly less marked. The exposures were, of course, made on the same individual.

Table Showing Results of Detailed Observations.

6·7	,,	15′	100	,,	,,	,,

1 E results in + + erythema in 24 hours and + + pigmentation in one week.

An attempt was made to obtain a direct skin reaction with rays of a particular wave-length by employing filters. A combination of Wood's glass and a vaseline cell showing spectroscopically absorption of all wave-lengths but a short band from 3800–3650 Å.U. was used (Fig. 1, No. 6). With this filter it was necessary to give 20 times the control exposure in order to get a faint transient erythema. It is possible that, in spite of the spectrographic evidence of the predominance of line 3650 Å.U., some shorter wave-length rays may have penetrated the screen and caused this effect.

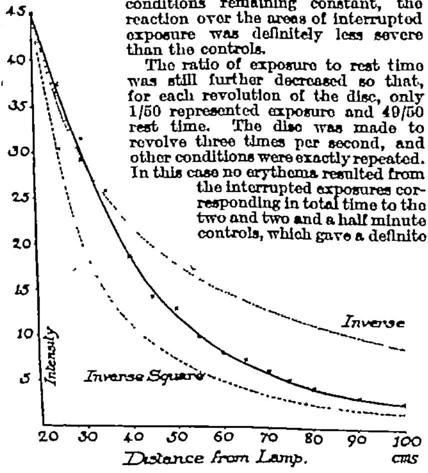
Cumulative Effect of Repeated Small Doses.

The next thing investigated was the cumulative effect of repeated small doses. The method of investigation was to interpose a revolving disc between the source of radiation and the skin under examination. By variation of an aperture in the disc, different ratios of "exposure" to "rest" interval can be obtained and the frequency of exposure varied by the rate of revolution of the disc.

It was found that, with a ratio of exposure to rest interval of 1 to 1 a purely cumulative effect is produced. With 1/10 exposure to 9/10 rest, when the revolutions were increased to three per second, other conditions remaining constant, the reaction over the areas of interrupted exposure was definitely less severe than the controls.

The ratio of exposure to rest time was still further decreased so that, for each revolution of the disc, only 1/50 represented exposure and 49/50 rest time. The disc was made to revolve three times per second, and other conditions were exactly repeated. In this case no erythema resulted from the interrupted exposures corresponding in total time to the two and two and a half minute controls, which gave a definite erythema within a few hours. The interrupted exposure corresponding to the three-minute control showed an erythema corresponding to the two-minute control. A further interrupted exposure of total time equal to a control of three and a half minutes resulted in an erythema corresponding to that of the two and a half minute control.

FIG. 2.



Thus it appears that, for the shorter exposures (two and two and a half minutes total time) a ratio of "exposure" to "rest" time of 1 to 50 does not result in a cumulative effect as far as erythema reaction and subsequent pigmentation is concerned; but the tissues have had the same actual exposure to the rays as would result in a definite burn if given as a continuous exposure. A continuation of observations with still further reduction of the momentary exposures is being made, but the times of exposure are necessarily very prolonged. Perthes[3] has shown that, when two doses of U.V. radiation are given to the skin with a long time-interval between them, less reaction is produced than if the whole dose is given at one time.

The possibility of a constitutional effect of repeated exposure of rats to ultra-violet rays was investigated on the following lines:—

A group of 40 animals of similar age, size, weight, and colour was selected and divided into two subgroups, 20 for experiment (Group I.) and the remaining 20 for control examination (Group II.). The males and females were segregated in each instance. The hair over the backs of the Group I. animals was cut short so as to obviate the dissipation of ultra-violet rays by fluorescence or heat production in the hair. These animals were exposed to the full radiation from the mercury-vapour lamp for five minutes daily at 50 cm. distance for 30 days. The power consumption of the lamp was 180 watts, giving a daily dose of ¼ E and a total dose of 7·5 E.

The animals in both Groups I. and II. received similar food and were housed under the same conditions as regards temperature, &c. Bi-weekly weight measurements show about 10 per cent. slower rate of growth in Group I. animals. At the end of one month the exposures were stopped, and one week later all the animals of both groups were inoculated with Jensen's rat sarcoma (J.R.S.) on the right side and with slow sarcoma on the left. Tumour measurements over a period of six weeks showed no appreciable difference between Groups I. and II. Thus it appears that, within the limits of the experiment, there was no constitutional effect calculated either to resist or favour tumour growth. A second series on similar lines gave the same result.

An attempt was made to find the lethal dose of ultra-violet rays for J.R.S. in vitro.

In view of the rapid absorption of the rays by the tissue, the sections of tumour must be very thin. To obtain a sufficiently thin uniform section to allow the rays to penetrate effectively, two razor blades were soldered to a metal handle so that the cutting edges were 0·5 mm. apart. With this double razor, sections were cut from actively growing tumours, care being taken to avoid any necrotic areas. The sections were laid flat, and, with due aseptic precautions, were treated as follows:—

Sections (*a*) were exposed to the full radiation from the mercury-vapour lamp.

Sections (*b*) were screened by 1·5 mm. of glass, to exclude the majority of the U.V. rays.

Sections (*c*) were set aside during the exposure and were used as controls.

A range of doses from 0·6 to 6 E was employed, the material being subsequently inoculated into batches of animals. When 6 E was reached all the (*a*) inoculations either failed to grow at all or grew small tumours for about ten days and then disappeared (0 per cent. growth). The (*b*) inoculations showed 33⅓ per cent. of growth, while the controls (*c*) gave 66⅔ per cent. growth. The lesser doses of U.V. rays allowed some growth in an appreciable number of cases, but 6 E was found to correspond to the lethal dose.

Conclusions.

From the foregoing experiments, it is, I think, possible to draw certain conclusions.

1. Since the skin surface is rendered visible by fluorescence, when only the invisible ultra-violet rays fall upon it, it is obvious that a greater or less amount of the incident rays is being dissipated at the skin surface as light and is consequently incapable of acting on any deeper structures.

2. Since fluorescence commences directly the skin is exposed to ultra-violet rays, whereas pigmentation only occurs as a result of considerable exposure, it is logical to suppose that, in fluorescence, we have a more immediate protection from excessive radiation, as far as ultra-violet is concerned, than in pigmentation.

---

[3] Perthes, G.: Münch. Med. Wochenschrift, Sept. 19th, 1924, p. 1301.

3. Since all the fluorescent substances examined, as well as the melanin which causes pigmentation, show marked absorption of ultra-violet rays, and since fluorescence and pigmentation always seem to vary inversely as each other, it might be interpreted that pigmentation marks the failure of fluorescence to protect the structures of the cutis vera from excessive radiation. This is substantiated by the experiments on artificially increased fluorescence, where no pigmentation followed exposure.

4. If pigmentation of the patient is aimed at as a standard of successful treatment, this is tantamount to producing deliberately in the patient a natural and efficient protection against the very source of treatment employed.

5. The pigmentation must be regarded as an indication that the penetration of the rays has not been prevented by fluorescence at the skin surface. If pigmentation could be avoided without hindering the penetration of the rays to the cutis vera it might prove more beneficial.

6. By employing the maximum dose which will on each application just fail to produce pigmentation, and, by separating the exposures by the minimum time-interval necessary to avoid the cumulative effect referred to, it should be possible to get equally good, if not better, therapeutic results in a shorter time.

I wish to thank Prof. Russ for his criticism and advice over many points in connexion with this paper, and Mr. D. B. Watters for assistance in measurements of intensity of radiation. My thanks are also due to Mr. S. J. Graham who kindly volunteered to submit to skin exposures in the majority of the experimental work.

SPIROCHÆTAL JAUNDICE IN GREAT BRITAIN.

BY EDWARD HINDLE, M.A. CAMB., PH.D.,
MILNER RESEARCH FELLOW, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE;

AND

H. C. BROWN, C.I.E., M.B., B.CH. CAMB.,
MAJOR, I.M.S. (RETD.),
WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

ALTHOUGH epidemics of spirochætal jaundice or Weil's disease seem to have been known from early times, especially during the Napoleonic and other wars, it was not until the discovery of the causative organism, *Leptospira icterohæmorrhagiæ*, by Inada and his fellow workers (1916) that the disease could be distinguished with certainty from allied conditions. During the great war the occurrence of considerable outbreaks attended by a mortality varying in different localities from 4 to 10 per cent. brought this disease into prominence,[1] and the works on the subject, such as those of Dawson, Hume, and Bedson (1917), and Martin and Pettit (1919), have considerably added to our knowledge. It seems to have been generally assumed that this was essentially a war disease and, as far as we are aware, its presence amongst the civil population in this country has only been proved on three occasions.

The first case was that described by Manson-Bahr, Wenyon, and Brown (1922) of a bargee who apparently became infected as the result of having swallowed large quantities of Thames water. The first appreciable epidemic in this country which was proved pathologically was that which occurred amongst the Lothian miners described by Buchanan (1924). Finally Lyon and Buchanan recorded a small outbreak in children in Edinburgh which, in their opinion, was the result of infection being introduced by a child from the Malay States.

In spite of the foregoing observations being the only proved cases recorded in this country, we strongly suspect that the disease is much more prevalent than is commonly supposed. Cases of slight jaundice, especially in children, preceded by febrile symptoms are well known. The common diagnosis is influenza followed by jaundice, but in view of the results of the case which we have examined, we suggest the probability of these being mild cases of spirochætal jaundice.

We have recently had the opportunity of examining two cases of this nature, in one of which we were able to demonstrate the presence of the very characteristic leptospira in the patient's urine. These cases are particularly interesting, inasmuch as they were undoubtedly linked up with a small outbreak in a school in the Midlands.

Clinical Records.

The clinical course of the disease in these two patients was as follows.

Case A, a boy of 12 years, returned from school for the holidays early in April. Fifteen days later he complained of headache, and for two days his temperature was raised, on the third day there was no fever, but on the fourth day the temperature again rose to 101° F.; this was accompanied by persistent vomiting, marked distaste for any sweetened articles of diet, distinct smell of acetone in the breath, and the urine contained considerable amounts of acetone as evidenced by Rothera's test. The vomiting persisted for four days, then during the second week of the disease jaundice was well marked; this was accompanied by pain over the region of the right kidney, and on examination of the urine a heavy cloud of albumin and red blood cells were present; the nature of the disease was not suspected and no examination of the urine was made for the presence of leptospira. The treatment was entirely symptomatic, the acidosis being combated by rectal injections of glucose and bicarbonate of soda. During the second week epistaxis was a marked symptom. The symptoms gradually cleared up, and the patient made an uninterrupted but somewhat tardy recovery and returned to school.

It was then ascertained that several other cases of jaundice, 14 in all, had occurred amongst the boys from the school.

Case B, sister of the above, aged 8, who had been in close contact with the previous case, showed febrile symptoms exactly 30 days after Case A first became ill. There was three days' high fever during which marked photophobia and conjunctival congestion was present; jaundice appeared during the second week of the disease. From the eighth to the seventeenth day careful daily examination was made for the presence of leptospira in the urine. They were only once found—namely, on the ninth day; but on this occasion they were present in very considerable numbers, there being as many as three in a field of the centrifuged deposit.

The other significant symptoms in this case were as follows. Epistaxis occurred at intervals during the second week. There was, however, no vomiting and no hæmaturia, and although acetone was present from the third to the tenth day in large amounts in the urine, the albuminuria was very slight, only amounting to a distinct trace, and even that was not always present.

Animal Experiments.

Although certain of the guinea-pigs inoculated with the deposit from the centrifuged urine showed febrile reactions indistinguishable from those occurring in typical cases of this infection, we have not yet been able to recover the leptospira from the inoculated guinea-pigs.

Three guinea-pigs were inoculated with centrifuged urine on the eighth day of disease; one of these, which showed marked febrile reaction, was killed on the sixth day after the inoculation. Portions of the liver and kidney were macerated in normal saline solution, and two more guinea-pigs were inoculated with this suspension. Cultures from the heart blood, and from the saline suspension, were taken into Wenyon-Noguchi medium, but no growth of leptospira occurred. Two more guinea-pigs were inoculated with centrifuged urine on the eleventh day of disease; one of these showed a febrile reaction indistinguishable from a typical case of spirochætal jaundice in this animal. This was killed on the seventh day, and the kidney-liver suspension inoculated into two more animals.

Unfortunately no animals were inoculated on the ninth day of disease. Of the three which had been inoculated on the previous day, one was showing a marked febrile reaction, and it was not then considered that the excretion of leptospira would prove to be such a transitory phenomenon in this case.

---

[1] In Japan a mortality of 57 per cent. has been recorded, but this seems to be very exceptional.

Source of the Infection.

It was found that four boys were admitted to the school sanatorium during the last week in March with symptoms very similar to those already described; also during the Easter holidays ten more boys suffered from a slight febrile condition, accompanied with jaundice in varying intensity and duration. Further, in addition to Case B, the sister of one of the infected boys also developed fever and jaundice. We therefore paid a visit to the school with the object of trying to discover some focus of infection. A similar outbreak in a school near Magdeburg (Körner, 1925) having been traced to infection through bathing, this possibility naturally occurred to us, but it was found that the school swimming tank had not been used by any of the boys during the last term.

Samples of water were taken from the storage tanks and also from the main water-supply, but in no case were leptospira found by direct examination of the centrifuged deposit. The cultures of the water from two storage tanks, however, revealed the presence of typical leptospira, but as these organisms have been found by one of us (E. H.) in water from many different sources, including London tap-water, its presence in this connexion does not necessarily throw any further light on the origin of this epidemic. The possibility of rats serving as a source of infection seems to be eliminated, as there was no record of any ever having been seen in the school buildings.

It is interesting to note that the four boys who first became ill during the term all occupied separate dormitories, and not one of the four was in the same form as the others. It would therefore appear that food or water was the most probable source of infection. As regards the chance of infection by food, there was a history of ambulatory indisposition in the case of one of the kitchen staff shortly before the boys became ill, but as 2½ months had elapsed before our visit, we were unable to obtain any more definite information on the nature of the illness.

Discussion of Results.

There can be no doubt that the cases which we have observed formed part of the general outbreak which originated at the school. We are led to this conclusion from the study of the history and clinical aspect. The incubation period in Case A was clearly a fortnight or more, a period which is considerably in excess of that usually observed in ordinary outbreaks of the disease. A similarly prolonged incubation period was also noticed in the case of some of the other boys, and this indicates that in mild epidemics, to which children seem to be specially liable, the incubation period may be as much as a fortnight or longer.

The clinical symptoms of both the cases observed by us closely resemble those described by Lyon (1925) in the Edinburgh epidemic last year. Acetonuria, epistaxis, and hæmaturia accompanied the jaundice and, in Case B, the conjunctival congestion mentioned by Stokes and Ryle (1916) and Martin and Pettit (1919) as being a feature of this disease.

The discovery of typical *Leptospira icterohæmorrhagiæ* in the urine of Case B on the ninth day of the disease leaves no doubt regarding the diagnosis. We are well aware that spirochætes of the *refringens* type have been found in the urine of normal individuals, but these bear no resemblance whatever to leptospira; with regard to *Spirochæta lorient* described by Pettit (1917) and Cristau (1917), which is apparently the cause of a very contagious spirochætosis, the high incidence of jaundice in the epidemic which we have described seems to distinguish it from the epidemic at Lorient.

From the figures given by Pettit (1917) it is impossible to distinguish these two species on morphological grounds. The fact that we have been unable up to the present to recover the organism from inoculated guinea-pigs does not in any way negative the diagnosis, for it is well known that when one is dealing with a comparatively non-virulent strain the chance of animal infection is remote. In the Edinburgh outbreak Buchanan (1925) only obtained one definitely positive result out of 44 animal experiments.

The main object of this paper is to emphasise the necessity of repeated examination of the urine for leptospira in all cases of undiagnosed fever followed by jaundice. This, however, can only be undertaken in a well-equipped laboratory, as a high-speed centrifuge and dark-ground illumination are essential. Finally, attention should be drawn to the infectious nature of the disease, and we suggest the advisability of adding it to the list of notifiable diseases, as from what we have heard recently there is some evidence that a mild form of this disease is widespread in this country.

THE CHAULMOOGRA TREATMENT OF LEPROSY

AT THE HOSPITAL FOR LEPERS, DICHPALLI, HYDERABAD STATE.

BY ISABEL KERR, M.B., CH.B. ABERD.

FOR the past four and a half years we have been giving the more recent preparations of chaulmoogra and hydnocarpus oil at this hospital, a mission institution which, in its erection and maintenance, owes very much to the enlightened generous policy of H.E.H. the Nizam and his Government.

Before the present treatment was adopted our inmates were mostly very advanced cases—men and women who, because of the deformity caused by the disease, were unwelcome in their homes. We could give them very little beyond general care, food, and clothing. They were unhappy because of their disease and we because of our ignorance of it. Such an institution achieves little or nothing in the prevention of the spread of leprosy, since most of the cases are past the infectious stages of the disease.

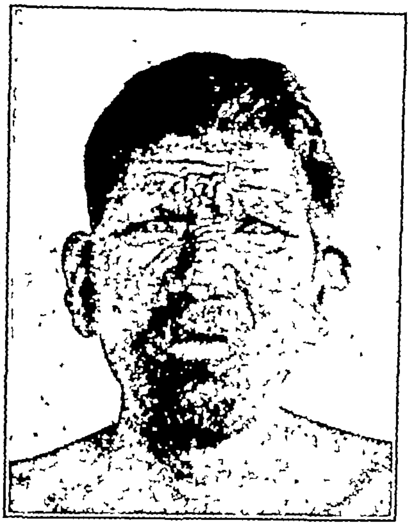
Methods of Treatment.

Early in 1921 we began the use of the ethyl ester of the fatty acids of hydnocarpus wightiana oil with creosote, camphor, and olive oil (E.C.C.O.), given under the skin or into the muscles. Of all the cases treated charts showing the condition of the patients were prepared—anæsthesia, nodules, discoloration, bacterial examination being recorded previous to treatment. Progress also was noted on successive similar charts. These were submitted to Dr. E. Muir, leprosy research worker of the Indian Government, Calcutta, with whom we have always worked in unison.

With the above preparation recent patches improved and nodules disappeared, but it was the general effect of this mixture which was most marked. It contained only a small percentage of ethyl ester. The exact composition was: Ester 1 part, camphor 1 part, creosote 1 part, olive oil 2½ parts, and the maximum dose, 5 c.cm. Previous to its administration our inmates were dull and apathetic, few of them slept, few had any appetite, and all were lethargic. The change was very marked; sleep and appetite returned and there was a general desire to move about and share in the normal activities of life. Both they and we felt we had come to the end of the dark tunnel in which we had been living, and had begun to see light.

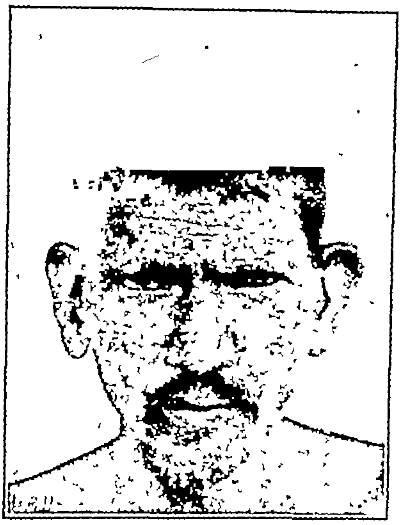
In order to check how much of the improvement was due to the creosote and olive oil we carried out a control treatment at the same time with a 2 per cent. mixture of creosote and olive oil. With this, sensation returned in non-sensitive areas of not too long-standing, but positive lesions did not show improvement as they did with E.C.O.O.

FIG. 1.



Before treatment.

FIG. 2.



After treatment.

From E.C.O.O. we passed to more intensive treatment, giving the pure ester combined with creosote and iodine intramuscularly, and with iodine alone intravenously. In this way we could give up to 16 c.cm. a week. By this time, too, we had begun to get a better class of patients; the Railway Medical Service of the State and our mission hospitals throughout the district combed out from their employees and their schools infected people. As many of these were early cases, we had just the sort of patient who responded to treatment in a comparatively short time. The intravenous method, though more speedy in its result, was not popular with a few of the patients, since it caused a good deal of nocturnal coughing. It did so also during injection if not given very, very slowly. In some of the acute skin ("nodular") cases it was difficult to give in small enough dose to avoid aggravating the disease, but the skin cases who could take the large doses, either intravenously or intramuscularly or both, did very well. The lepra bacilli, lying as they do as emboli in the fine capillaries, can be reached through the blood-stream. In nerve cases the organisms are more difficult to reach. With them results were not so marked. However, of the reports and charts we submitted to the Leprosy Research Department, Calcutta, 66 per cent. of our cases showed "very much improvement," and of these 12 per cent. had become symptom-free.

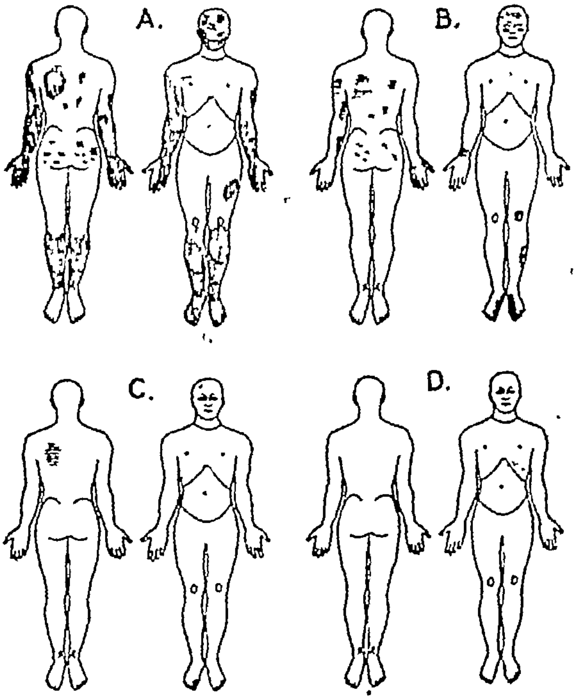
I may say at this point we accelerated the effect of the ester by the use of Kedrowsky vaccine. Dr. Muir kindly supplied us with slants of the "lepra bacilli" from which we had vaccines prepared. This started cases reacting (i.e., getting evening temperature) after they had seemed callous to the ester.

Occasionally one finds a case which cannot take this treatment. One we had was a young man of 25 who had suffered from constipation from his childhood, had hæmorrhoids, and a liver which refused to function. Under such conditions it was impossible to coax even the beginnings of immunity without causing a violent reaction which was difficult to stop. We like to keep our patients, when we can, just on the point of reacting, even although we find that a reaction of 48 hours can bring about a great deal of improvement. Invariably we find that minimum doses of the E.C.O.O. 0·25 c.cm. brings down the temperature. For this it is a valuable asset as well as for infiltrating old bone lesions which cause perforating ulcers.

Of course to achieve success we have been careful to get our cases uncomplicated. Concurrent disease, such as intestinal worms, malaria, syphilis, chronic gastric trouble, hinder the patient acquiring immunity. A quantity of medicine is wasted and prolonged inconvenience to the patient caused if these are not dealt with.

The more recent method of infiltrating the skin with the ester combined with creosote or thymol has given the quickest results with us at Dichpalli and, I believe, elsewhere. No inconvenience beyond a burning sensation for a few minutes at the points of injection is felt, and thus the patients are very keen about it. We infiltrate the lesions with the drug and paint over the surface with trichloracetic acid. Early cases show improvement within a few weeks; older lesions naturally need longer time. Very old nerve lesions, where the nerve-endings are dead, cannot improve. The scars may disfigure the patient, but, being non-infective, they can no more

FIG. 3.



Effects of modern treatment in an early case of leprosy.

A, on admission (1/6/21). Showing erythematous patches of imperfect sensation; lepra bacilli in nasal discharge. B (1/2/22). Showing discoloration of old patches and some small insensitive areas. C (30/3/22). Discoloured patch on back and small insensitive patch on toe. Nose shows broken-up bacilli. D (10/8/22). Patient symptom-free. Wassermann test negative.

convey leprosy than, as Dr. Muir has put it, can small-pox pitting convey small-pox.

When a lesion is infiltrated we find that not only is there improvement locally, but also in the distant lesions. The irritation caused by the drug breaks up the bacilli which throw out their toxins. Those again make antitoxins which break down bacilli elsewhere. By infiltration we can give whatever amount of the ester a patient can take. As much as 20 c.cm. can be given a week and even more. We generally give part of a large injection into a muscle.

This short article would be incomplete without reference to a control treatment we carried out for two years with the esters of linseed and olive oil. This was done at the suggestion of the Calcutta leprologists. With a few cases—mostly nerve leprosy—improvement followed, but not so marked as with the chaulmoogra series. All these oils are unsaturated, but linseed and olive oils do not belong to the carbon ring series as do the latter. As leprologists tell us, we need both qualities in then treatment of leprosy, and our control treatment bears this out.

Results.

Out of 180 patients treated with hydnocarpus ester during 1923 and 1924 the following statistics were drawn up: 17 per cent. symptom-free; 45 per cent. very much improved, most of them likely to become symptom-free; 35 per cent. improved; 3 per cent. worse or dead. Of infective cases 63 per cent. have become non-infective.

In all skin cases the effects of treatment are gauged by microscopic examination of skin and nose. It is important with such patients that the treatment should be as intensive as possible. If it is slow the nerves may become affected, and the treatment would be unnecessarily prolonged.

On admission a number of our patients suffer from acute toxæmic symptoms—temperature and pain along the nerve trunks. This is especially marked if the disease is not advanced. Even with the minimal doses, which one has to give to avoid aggravating the temperature, the neuralgic symptoms disappear almost as if a dose of morphia had been given. When the progress of the disease has been stayed the patient's immunity increases and we are able to give larger amounts of the drug. The results then depend on patience, care, and time. Two complications for which we have to be on the look-out are tuberculosis and nephritis. The symptoms of tubercle are often so completely masked by those of leprosy that the first announcement of its presence may be acute tuberculosis of the intestinal or meningeal type.

The series of diagrams, A to D, show what may be expected in an early case of leprosy which had just passed into the infective stage. There was obstruction of the right nostril, occasional bleeding, and acid-fast bacilli in smear. The symptoms appeared concurrently with an attack of syphilis. The longitudinal shading represents loss of sensation; horizontal shading discoloration. The patient was under intensive treatment for 15 months. Then he returned to normal life and work, coming to us for a time for weekly injections. He has kept perfect health for three years.

LECTURES ON CHILD WELFARE.—The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy has arranged a special course of lectures for health visitors, voluntary workers, teachers, nurses, &c., to be held at University College, Nottingham, from Sept. 21st to 25th. The syllabus includes such lectures as the Nervous Child, by Dr. Eric Pritchard; the Care of the Adolescent Girl and the Home Care of the Mentally Deficient, by Dr. Letitia Fairfield; the Prevention of Difficulty in Labour, by Dr. J. S. Fairbairn; Ductless Glands and Vitamins, by Dr. J. Stanley White; and Warnings of the Abnormal in Labour, by Lady Barrett. Visits to clinics, sanatoriums, and dwellings will also be included. Full particulars may be obtained from the Honorary Secretary, 117, Piccadilly, W. 1. Early application is advisable.

TWO CASES OF CYSTINURIA IN CHILDREN,

WITH RENAL AND VESICAL CYSTIN CALCULI RESPECTIVELY.

By J. F. H. STALLMAN, M.B., B.S. LOND., F.R.C.S. ENG.,

CLINICAL ASSISTANT, LATE SURGICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON; SURGICAL REGISTRAR, LONDON TEMPERANCE HOSPITAL.

CYSTINURIA is a rare family and hereditary abnormality in the metabolism of proteins,[1] in which the sulphur-containing amino-acid, cystin, a normal product of the hydrolysis of proteins, is excreted in the urine to the extent of half a gramme in the 24 hours. It is found in the child, and persists throughout life.[2] Cystin may give rise to urinary deposits in acid urine in the form of colourless hexagonal plates and may form calculi. The deposit alone, however, will not form calculi, but is only a factor in their formation.[3] Apart from the liability to form calculi, the excretion of cystin has apparently no ill-effect; thus Abderhalden[4] says: "The metabolism of a cystinuria patient is always normal, and urinary stones are frequently found in the disease." Macalpine,[5] who removed six cystin calculi from the kidney of a boy aged 8 years, noted that the urine of cystinurics on decomposition had a foul odour, possibly due to the sulphuretted hydrogen produced during the decomposition of the cystin, which contains practically all the sulphur of proteins.

The calculi are of a yellow appearance, and assume a greenish waxy appearance after removal. They are often multiple and bilateral, and may be found either in the kidneys or bladder, and are prone to occur in several members of the same family. They usually cast a fairly dense shadow with the X rays. Case 1, here reported, gave excellent shadows. Graves,[6] however, reported a case in an obese woman of 26 with unmistakable clinical signs of calculus in the kidney, which failed to reveal a shadow on two occasions. It was finally shown by a pyelogram. He points out that cystin, being an amino-solid, would not be expected to give a shadow unless mixed with inorganic substances. Thomson-Walker[6] says that "cystin and xanthin calculi cast a shadow only slightly less dense" than oxalate of lime calculi. Graves, however, admits that the general opinion of most writers is that they readily give a shadow, and quotes Müller,[7] who reported a case of a man, aged 21, who persistently formed cystin calculi which gave shadows with the X rays. He also refers to Morris's[8] paper on the X Ray Shadows of Cystic and Xanthic Oxide Calculi. Morris said that many cystin calculi contain phosphate of lime and traces of magnesium and ammonium phosphate, but what was more to the point, cystin contains 25·58 or 25·81 per cent. of sulphur, and therefore it was improbable that they could fail to cast a very deep shadow. He reports a case in a patient, and refers to specimens in the Museum of the Royal College of Surgeons of England.

Frequency of Occurrence.

As regards the frequency of occurrence of cystin calculi, Tennant,[9] in his paper on cystin calculi, says that until 1882 only 50 cases had been reported. He refers to Kretschmer's[10] comprehensive study on cystinuria and cystin calculi in 1916. He (the latter) found 107 cases of stones, including two of his own in twin boys aged 9 years. Vesical calculi were present in both the twins and were diagnosed before operation. Tennant also refers to Watson and Cunningham,[11] who reported one case in 32 cases of cystinuria, to Morris[12] two in 77, and to Sir Henry Thompson three in 114. Calculi, therefore, occur in about 2–3 per cent. of cystinurics. Although rarely, calculi may occur in old age. Mörner[13] reported a vesical cystin stone successfully removed from a man aged 69.

As regards the families of the two cases here recorded, a baby sister of Case 1 is cystinuric, but other members of the family, including both parents, are free from this anomaly. A brother of Case 2 passes urine containing cystin, but the urine of the mother (father deceased) contains none. It may be noted [14] that the urine must be acid for the deposition of the crystals, and if not acid must be rendered so by the addition of a few drops of acetic acid.

Cystinuria is of interest to the surgeon on account of the complex surgical problem that is presented so frequently by the multiplicity of the calculi and by the persistence of their re-formation after removal. These two factors are responsible for serious damage to the renal function, and establish thereby a grave operative risk. Thus Tennant,[9] in his paper referred to above, reported a case of multiple cystin calculi in a woman aged 21, on whom he performed three major operations, removing 15 large stones of an aggregate weight of 73 g., and involving both kidneys and one ureter. There were two in the right kidney, one in the left, and a series of 12 in the right ureter. The function of the right kidney was low, as shown by the phenolsulphonephthalein test. She recovered, but continued to deposit cystin crystals in the urine. Müller,[7] in his paper already quoted, gives the history of a young man of 21, who formed cystin calculi with ungovernable persistence.

CASE 1.

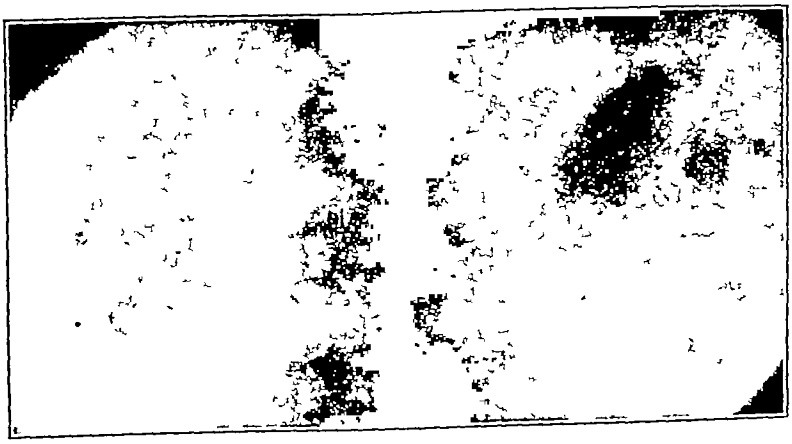
Case 1 is an illustration of the surgical problem with which the surgeon may be faced. This case was under the care of Mr. George E. Waugh at the Hospital for Sick Children, Great Ormond-street, to whom I am indebted for permission to publish it, and whom I have to thank for many suggestions and much helpful criticism in the preparation of this paper.

CASE 1.—K. H., girl, aged 9⁹/₁₂ years, was admitted to hospital on March 20th, 1922, with a history of pain in the right side for about a year, and occasional hæmaturia after running about.

Past and Family Histories—Nothing of note, but subsequently in February, 1924, a baby sister was found to be passing cystin.

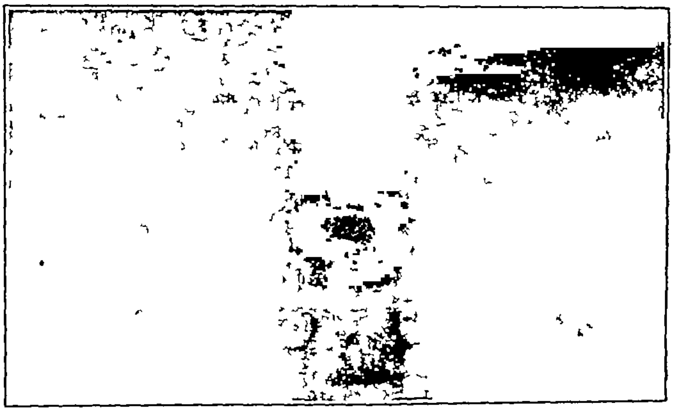
Condition on Admission.—She was a pale but well-nourished child. Right kidney easily palpable. No œdema of the extremities or puffiness under the eyes. Urine: Pale, turbid, acid; sp. gr. 1012; albumin, slight cloud; no sugar. Blood cells, occasional pus cells, and granular casts present. Blood pressure. 123 mm. Hg. Wassermann reaction: negative. No retinitis. Skiagram: One large calculus and several smaller ones in the pelvis of each kidney (Fig. 1). Urea-concentration test (March 24th, 1922): Maximum urea concentration of 1·7 per cent. Cystoscopy (March 31st): Nothing abnormal. Ureters catheterised. 2 P.M., 4 c.cm. of 4 per cent. indigo-carmine given intramuscularly. 3.40 P.M., coloured urine from right kidney. 6 P.M., tinge of colour from left kidney. Segregated urines: Urine from right kidney, urea present in considerable quantity; urine from left kidney, urea present in minute quantity. Conclusion: Right kidney, fair efficiency, 60 per cent. of normal; left kidney, poor efficiency, 10 per cent. of normal.

FIG. 1.



Case 1.—Skiagram, March, 1922. Calculi before operation

FIG. 2.



Case 1.—Skiagram, July, 1922. Calculi remaining after both operations, and before administration of sod. bicarbonate. (Cf. Fig. 3.)

First operation (April 7th): Left kidney (more damaged one). Usual lumbar incision. One large branched calculus, about five or six smaller ones, and many minute calculi were removed from the pelvis of the kidney, which was considerably dilated, the amount of kidney substance being considerably reduced. Difficulty was experienced in removing the smaller stones from the dilated calyces. The pelvis contained purulent urine and was irrigated with 2 per cent. chloramine in saline and closed with drainage. During the operation the parietal wound was protected with gauze wrung out in 1 in 40 carbolic acid to avoid infection.

Pathological report on calculi: Cystin calculi; the large branched one weighed 15·50 g. Urine: Cystin crystals found in the deposit.

Urea-concentration test (April 24th):—

	Patient.	Control.
24-hours specimen ..	0 6 per cent. urea	1 8 per cent. urea.
Grammes vi. urea given :—		
6 A.M...	1·7 " " "	2 9 " " "
7 A.M...	1 4 " " "	3·1 " " "
8 A.M...	1·3 " " "	3 2 " " "

Skiagram (May 18th): Several small stones still remain in the pelvis of the left kidney

Second operation (May 10th): Right kidney. A similar operation was performed, and the same condition found as in the left kidney; but the kidney was not so dilated. Large branched calculus, weighed 6 40 g. After both operations there was considerable hæmaturia for some days, which, however, cleared up without trouble, and the wounds healed soundly after removal of the drainage-tubes, without becoming infected. July 5th, numerous minute calculi passed during the last month. Skiagram: Several small calculi remain in the pelves of both kidneys. Ureters and bladder free. (Fig. 2.) Urea-concentration test: 24 hours specimen, 1 1 per cent. urea; 4 A.M., 1·4 per cent. urea; 5 A.M., 1·8 per cent. urea; 6 A.M., 1 8 per cent. urea. Oct. 9th, passing small stones at intervals, sometimes hæmaturia. Skiagram: No change since July. Urea-concentration test: Maximum urea-concentration, 1 8 per cent. Diet: Fish; sod. bicarb., gr. 120 daily

February, 1923: Occasional severe headache, occasionally passes a small stone. Urea-concentration test: 24 hours specimen, 1·75 per cent. urea; 6 A.M., 1·45 per cent. urea; 7 A.M., 1 70 per cent. urea; 8 A.M., 1 80 per cent. urea.

February, 1924: General condition improved, and she is growing. She attends school, but still has severe headaches which keep her away on occasions. Has not passed any stones for fully six months.

Urea-concentration test:—

	Urea per cent.	Urine.
Twenty-four hours urine	1·31	508 c.cm.
First hour	1·50	90 ,,
Second hour	1·40	150 ,,
Third hour	1·58	90 ,,

Urine contains cystin crystals, no casts; cultures sterile. Skiagram: Now remaining, one large and one small calculus in the left kidney. (Fig. 3.)

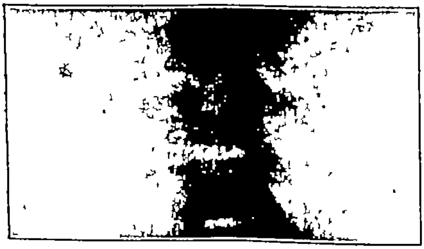
December, 1924: Condition excellent, attends school regularly. Cystin crystals still present, but as precipitation. Diet restricted still and 120 gr. sod. bicarb. daily.

Comment.

The urea-concentration test, the indigo-carmine test, and the analysis of the segregated urines, showed a low renal efficiency and therefore a bad operative risk. It was, however, essential to attempt removal of the stones, the alternative being inevitable death within a comparatively short period.

The surgical problem presented was the question as to which kidney to operate on first. To operate upon the more efficient kidney first with a view to arresting further damage to the renal structure as quickly as possible, would appear to have been the operation of choice. But the fear that suppression of urine might follow the first operation was responsible for the decision to deal with the less efficient kidney first, thus leaving the more actively functioning kidney to bear the brunt of a possible post-operative complication. The subsequent after-course of the patient threw no light upon the wisdom of this decision. She did remarkably well after both operations; at no time did her condition give rise to anxiety, neither were there any signs of impending uræmia. No doubt this favourable result was largely due to careful nursing and dieting.

FIG. 3.



Case 1.—Skiagram, February, 1924, showing effect of administration of sod. bicarbonate. (Cf. Fig. 2.)

There was a measure of doubt as to whether the stones in the left kidney shown by the skiagram taken in May, 1922, just before the second operation, and in both kidneys in July and October, 1922, had been left behind at the operations, or had re-formed in the meantime. The skiagram in May was taken about six weeks after the first operation, and that in July about two months after the second, which seems a very short time for the calculi to have re-formed. But she was not put upon large doses of sod. bicarbonate daily until October, 1923, which is said to increase the solubility of cystin. It seems hard to confess that any stones had been left behind after the very thorough manner in which the calyces had been explored and irrigated. The skiagram taken in February, 1924, shows that she has been passing these stones, so that the sod. bicarbonate appears to have been of considerable value. The urine, however, still contains cystin crystals.

Prognosis.

Although the patient is lucky to have recovered from two severe major operations on such damaged kidneys (Kürster gives the mortality for double calculi as 35 per cent.), the ultimate prognosis cannot be very favourable. The urea-concentration test in February, 1923, shows very little improvement indeed in renal efficiency, while that of February, 1924, is distinctly disappointing; considering she has passed the majority of the stones remaining in the kidneys, one had hoped for an improvement in renal efficiency, more particularly as she has improved in general health, and is growing.

Apart from her renal efficiency, her present condition is encouraging, but the restricted diet and sod. bicarbonate must be continued. Should she form any calculi of such a size as to call for removal, operations on such damaged kidneys would be attended with very grave risks indeed.

The mother gives the following history of a sister of this patient:—

M. H., girl aged $1^{9}/_{12}$ years. Since July, 1923, has had attacks of abdominal pain accompanied by profuse sweats. She doubles herself up and presses the hands over the pubes. Each pain lasts from three to four minutes, and may occur several times daily. The relation to micturition has not been noted, and no blood in the urine has been seen. While under observation in the ward for a week in February, 1924, the attacks of pain were not noticed, but she appeared to have some retention on occasions. The urine was acid, contained an abundance of cystin crystals, and *Staphylococcus albus* was grown from a catheter specimen. A skiagram of the urinary tract was negative.

CASE 2.

Case 2 is that of a boy who was under the care of Mr. O. L. Addison at the Hospital for Sick Children, to whom I am indebted for permission to publish it.

C. H., boy aged $2^{7}/_{12}$ years, was admitted to the Hospital for Sick Children on Sept. 15th, 1922.

History.—Twenty-one months ago he started screaming when passing water; attacks of pain came on every two weeks at first, more frequently lately. He was always soaking his napkin. He passed a very little bright blood on two occasions in March or April, 1922, and for six weeks during March and April he had a urethral discharge. He was circumcised when six weeks old.

Family History.—Brother, E. H., aged 9, has had an operation for stone in the bladder elsewhere, which was not chemically examined. Father died from heart failure. Skiagram: Large vesical calculus. Cystoscopy (Sept. 21st, 1922): Stone seen, also two ulcers. Œdematous and inflamed mucous membrane. Bladder contracted. Suprapubic lithotomy: Stone size of a pigeon's egg removed. Drainage-tube inserted. Pathologist's report: Cystin calculus weighing 8 g. The drainage-tube was removed on Sept. 28th, and the boy discharged with the wound healed on Oct. 17th.

Readmitted on Oct. 28th, 1923, for "inability to pass water." Since discharged last year has been quite well, but recently has been wetting himself more than previously, having frequency at least every hour by day. Stream has always been good. Oct. 27th, 1923: Only a drop or two of urine would come away. A doctor passed a catheter and sent him to hospital. While being carried to hospital he had an attack of screaming. Mother examined him and found that two small stones had been passed. In the ward he appeared to be quite comfortable. Bladder was not distended. The stones were the size of a split pea, hard, and brittle. Skiagram (Oct. 3rd, 1923): Bladder and kidneys—no abnormality, ? doubtful shadows left kidney region. Passing urine freely. Urine: culture from deposit: first day, streptococci isolated; second day, few colonies. *B. proteus* grown. Report on calculi: Calcium oxalate and triple phosphate, trace of alkaline earths. No cystin. Cystoscopy (Nov. 1st): Slight cystitis. Area of left ureteric orifice inflamed. No stones seen. Skiagram (Nov. 5th): Very small shadows in left kidney region. January, 1924: Still has frequency, wets himself often. Urine deposit: Chiefly oxalate crystals, few cystin crystals. February: Put on sod. bicarb., gr. 45 daily. March: Has passed two more small calculi which the mother did not keep. Skiagram (March 22nd): Fairly large calculus in left kidney. December: Still wets himself. Passed some "sand" in

September last. Calculus little larger but still of a size possible of being passed. Still on sod. bicarb., gr. 45 daily.

Comment.

This case is remarkable in that the boy forms oxalate calculi as well as cystin, and that the urinary deposit contains chiefly oxalate crystals, only a few cystin crystals being found. In the literature I have searched, I have not found a case in which other calculi as well as cystin calculi have been formed.

Prognosis.

Unless this patient succeeds in passing the calculi now in his left kidney, it is evident that sooner or later they will have to be removed. Being a boy, he is less likely to pass them as the girl has done. Moreover, his bladder is infected, and, with the calculi, progressive loss of renal efficiency will ensue. That he forms two different sorts of calculi also complicates matters. But he has come under treatment before serious damage to his renal function has occurred, and so his outlook in life is considerably better than the girl's. E., the brother of this patient, who had a vesical calculus removed elsewhere four years ago, has no symptoms now, and a skiagram of his urinary tract is negative. His urine, however, contains cystin crystals. I think it, therefore, justifiable to assume that his calculus was of this composition. He has now been placed on sod. bicarbonate gr. 45 daily, with a view to preventing, if possible, any re-formation of cystin calculi.

SUMMARY.

Cystinuria, when complicated by the formation of calculi, is undoubtedly a very serious disease, both on account of the multiplicity of the stones and the serious damage to renal function caused thereby, and also on account of the persistence with which they continue to be formed. Their formation can evidently be controlled to a certain extent by the administration of large doses of sodium bicarbonate; but it is said to be largely independent of diet. Since only 2 to 3 per cent. of cystinurics form calculi, cystinuria cannot be looked upon as a very serious potential danger to life, and apparently 97–98 per cent. of these individuals go through life without suffering any disability at all from their abnormality in protein metabolism. It is possible, on the other hand, that, with the increase of biochemical investigations carried on in this branch of medicine, more unsuspected cases of cystin calculi may be discovered, since calculi have not always been subjected to analysis and the yellow appearance of cystin calculi at the time of removal may suggest a uric acid or urate composition. It is not until after exposure for some time to the air that they assume their characteristic greenish waxy appearance.

Since writing this paper Edwards[15] has published an interesting case of cystinuria with calculous formation, in whom the passage of cystin crystals was *intermittent*. Repeated specimens of urine gave no deposit of crystals after acidifying with acetic acid and acetone, and the chemical reactions of cystin were absent. The specimen containing crystals was darker and more oily than those without the crystals and yielded a heavy deposit. The familial nature of the disorder is also strongly brought out in his case, and a study of the family further emphasises the serious damage that can be done to the kidneys as well as the multiplicity of the stones that may be formed—over 200 having been found in the enormously enlarged kidney removed from one sister.

As regards the density of the X ray shadows of cystin calculi being dependent on the sulphur they contain, Winsbury White[16] states in a recent paper that cystin and xanthin calculi give poor shadows when in the pure state, but of slightly more opacity than those of urates, uric acid, and triple phosphate owing to the sulphur they contain.

Edwards also makes some suggestions as to treatment. He says that choleic acid may be given on the hypothesis that endogenous cystin is excreted because of the lack of choleic acid with which it should normally conjugate to become the taurin of the bile-salts. Intestinal and urinary antiseptics, he says, should be given to allay the pelvic infection which furnishes the irreversible colloid that glues the crystals into calculi. Vaccines prepared from fæcal strains for this purpose he did not find of much benefit. He also refers to Klemperer and Jacoby, who state that the administration of 6–10 g. of sodium bicarbonate causes the complete cessation of cystinuria. Where stones have already been formed this is of no value, but in the two cases here described the large doses given seem to have been of distinct value, in any case in controlling the formation of calculi.

New Inventions.

AN IMPROVED REFILL NEEDLE FOR ARTIFICIAL PNEUMOTHORAX.

THERE are certain disadvantages in the refill needles commonly used in cases of artificial pneumothorax. The Lillingston needle is difficult to push through the skin. The Saugman needle is very apt to punch out a piece of skin. This can easily be cleared by squeezing the tube, or inserting the stilette through a stuffing box, but it is a *nuisance*, and theoretically it is wrong to push the piece of punched-out skin into the pleural space. I have, *therefore*, asked Messrs. Allen and Hanburys to make for me the needle herewith illustrated. It works extremely well. The point is an ordinary sharp-cutting trocar point; the outlet hole is situated laterally. It can only be used, of course, when there is an appreciable pneumothorax.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF SURGERY.

WEDNESDAY, JULY 22ND.

CARCINOMA OF THE STOMACH.

IN opening a discussion on this subject Sir William I. de Courcy Wheeler reminded the meeting that 10,000 people died annually in the British Isles from this condition. He proceeded with a destructive criticism of the method of diagnosis by analysis of the gastric contents which, in his opinion, did not lead to any definite goal, nor did he consider the fractional test-meal productive of encouraging results. The greatest advance in diagnosis lay, he said, in accurate X ray examinations; though even here one must not expect the miraculous. He referred to the occurrence of venous thrombosis as a valuable sign of early carcinoma of the stomach (Prof. T. G. Moorhead), and cited four cases where its value was illustrated. The speaker was of the opinion that if there was no gain in weight, or at least maintenance of weight, after efficient medical treatment, malignant disease should be suspected and exploration was then more than justified. He recognised a definite "pernicious anæmia type" of carcinoma of the stomach, and held that should such cases not respond very rapidly to treatment by arsenic, malignant disease should be suspected. In dealing with the differential diagnosis, syphilis and gastric disturbances in pulmonary tuberculosis, diabetes and actinomycosis, were described as conditions likely to be confused with malignant disease of the stomach.

Proceeding to the question as to whether gastric ulcer was or was not a precursor of carcinoma, the speaker instanced several cases of undoubted implantation of carcinoma on a chronic ulcer, but admitted that most cases of carcinoma on which he had operated arose without symptoms which would suggest the presence of a previous ulcer. He did not believe that palliative operations were of much value. The value of radium in the treatment of carcinoma was undoubted. The two-stage operation for removal of the carcinoma was seldom, if ever, necessary, and he found the shock from gastrectomy of the Mayo-Moynihan-Polya type to be surprisingly small. Sir William Wheeler then described a very interesting case, in which he had removed, apparently, the whole stomach for a non-malignant ulcer. His address was illustrated by slides and X ray photographs.

Dr. E. I. Spriggs spoke of the

Clinical Manifestations and Early Diagnosis

of cancer of the stomach, excluding the use of laboratory methods. He first gave an account of the classical symptoms—vague discomfort occurring in elderly men, with gastric flatulence and loss of appetite gradually developing into nausea, eructation merging into vomiting, pain either in the pit of the stomach, the small of the back, or between the shoulders; then later, a tumour, loss of weight, colour, and vigour; and finally, ulceration, coffee-ground vomit, mild irregular fever, involvement of other structures, and death in two years. He compared these symptoms with those described in 25 chosen cases, in which a very full history was obtained. In 17 the history was recent; in four it was long. The history of old indigestion, he pointed out, must not be allowed to obscure the diagnosis. Dr. Spriggs compared the symptoms according to the part of the stomach involved. In cases where the carcinoma was situated at the cardiac end, eructation was more common than in other types. After a time the symptoms gradually merged into those of œsophageal obstruction. In cases of the "leather bottle" type, the patient early complained of an aversion to food. When the neoplasm was situated at the pyloric end of the stomach, there was always pain after food, which might, or might not, be relieved by more food. The history was never clear-cut. Vomiting of large quantities of food at intervals of two or three days, he considered, was a very rare sign in cases of malignant disease. In three of his cases hæmatemesis was the first evidence of the presence of malignant disease. An anxious expression was sometimes present, and, if present, was sufficiently characteristic to be an aid to diagnosis. Finally, the speaker expressed his opinion that the first most vital step towards a diagnosis of carcinoma was not the clinical study of the patient. He believed that investigation should be carried out at once—that there should be no "watching"—and that carcinoma should be excluded at the earliest possible moment. X ray examination he considered the most important. All examinations should be very complete, and if the diagnosis was still in doubt an exploratory operation should be performed.

Dr. A. F. Hurst dealt mainly with the methods of investigation of the patient. He strongly urged that doctors should send their pat'ents early to the radiographer, and that patients should be encouraged to come early to their doctors, even for vague pain. He discussed the methods of examination of the stomach content, chemical and microscopical. With reference to the examination for pus, he recommended routine examination of the "spittle." He considered that the presence of blood in every part of a fractional test-meal was evidence of malignant disease unless there had been a recent hæmorrhage from an ulcer. He was of the opinion that a skilled radiographer could show an abnormality of the stomach in 100 per cent. of cases of malignant disease. A fallacy was present if the stomach was not empty when the examination was made, for the barium might then appear low down, because it had sunk to the bottom of a full stomach. Occult blood was present in 100 per cent. of cases and the examination for its presence was of the utmost importance. It was never present in normal people, and although it was found in patients suffering from a gastric ulcer that condition could be distinguished by X ray examination. Examination of the blood for megalocytosis was important in the differential diagnosis of pernicious anæmia. Dr. Hurst showed slides illustrating this point and described a method of measuring the cells.

Pathology of Gastric Carcinoma.

Prof. M. J. Stewart dealt with the pathology of carcinoma of the stomach, the relation of ulcer to carcinoma, the mode of spread of the carcinoma, and the frequency of secondary deposits in the liver. He presented an analysis of 105 cases examined in the post-mortem room. Of these, 82 per cent. were between the ages of 40 and 70, and the proportion of males to females was 2 to 1. His address was illustrated by a series of microscopical specimens showing sections of chronic ulcer and of malignant disease. In a series of 216 clinical specimens of gastric ulcer and carcinoma 9 5 per cent. showed carcinoma implanted on a chronic ulcer.

Dr. Gregory Cole (New York) said that five years ago it was taught in America that 68 per cent. of cases of gastric ulcer became malignant. In one-tenth of the ulcer cases he had seen in the last ten years he could not say whether they were malignant or not, in the remaining 90 per cent. he had only seen one in which carcinoma developed in the neighbourhood of a chronic ulcer.

Mr. John Morley, although he considered the idea that carcinoma was often implanted on a chronic ulcer attractive and that it would lend point to the advice to patients to be investigated early, nevertheless doubted its truth. He drew attention to the possibility of a mistake in microscopical diagnosis in those cases where, as had been pointed out by Sir Bernard Spilsbury, there might be proliferation of cells at the edge of an ulcer. Where the history of indigestion was recent—under 12 months' duration—there was a strong likelihood of the presence of malignant disease. He was of the opinion that carcinoma originating in a chronic ulcer was rare.

Dr. W. D. Haggard (Tennessee) said that in dealing with ulcers the operation of wide excision with the cautery and subsequent examination was of great value. He believed in the two-stage operation in late cases. He said that in America they were still looking "like the wise men towards the East for inspiration."

Mr. A. H. Burgess (Manchester) considered early diagnosis of penultimate importance. Surgical treatment must, as always, aim at radical extirpation. He instanced ascites, secondary deposits in the liver or the peritoneum (which might be felt in Douglas's pouch by rectal examination) as contra-indications to radical operation. Fixity to the liver or to the pancreas were not necessarily contra-indications. If the middle colic artery was certain to be damaged, owing to extent of growth to be removed, he thought the case should be left alone. He considered palliative gastro-jejunostomy was indicated only if there was obstruction. He then dealt with the operative details and demonstrated a stomach clamp.

Dr. C. L. Starr (Toronto) emphasised the importance of not "watching." If glands were enlarged, cure was impossible. He did not believe in exploratory operations, except in a limited number of cases.

Mr. Garnet Wright considered that clinical evidence was mainly against the probability of the development of carcinoma on top of a chronic ulcer.

Mr. R. P. Rowlands described a case of primary tuberculous ulcer, which he had treated by resection. He did not consider exploration dangerous in early cases, nor did he think that damage to the middle colic artery was a serious matter.

Mr. H. S. Souttar described two "ludicrously" inoperable cases with which he had dealt, doing a gastro-jejunostomy in the one and a resection in the other, and had succeeded in giving both of them several months of comfortable life. He described and eulogised Schumacher's clamp.

Sir Berkeley Moynihan (President of the Section) stated that surgery had out-paced medicine in the treatment of carcinoma of the stomach. There was very little chance of improvement under medical treatment, but there must always be a certain mortality in cases operated upon. He did not consider that the omentum need be removed—in fact, he left it and used it as a cover for the field of operation. Operations of the type Billroth No. 1 were only suitable for ulcer cases. Examination should be made as often and as fully as possible. There were many methods of operation—each useful. Patients must always be made fit for their operation; there was no great hurry and time spent in transfusion of blood, glucose injections, artificial and real sunlight was time well spent indeed. The President considered that the profession should teach the public about carcinoma, and he put forward the suggestion that the Ministry of Health should send out doctors to preach the gospel of health. If it was suspected that a patient was threatened with carcinoma, the experts should be gathered around him at once.

The openers then briefly replied.

THURSDAY, JULY 23RD.

Treatment of Primary Acute Intestinal Obstruction.

A discussion on this subject was opened by Sir William Taylor (Regius Professor of Surgery, Dublin University). He stated that the surgery of the acute abdomen had advanced so satisfactorily during the past 25 years, with the sole exception of acute intestinal obstruction, that one was compelled to ask why the mortality from that condition was to-day no better than it was at the beginning of the century. He attributed this appalling state of affairs to the ignorance and carelessness, both inexcusable and nothing short of criminal, of the general practitioners and physicians, who see these unfortunate patients in the earlierst ages of their illness. Instead of realising that purgatives and enemata could do no good, but, on the other hand, might do infinite harm—apart from the delay in surgical treatment their administration entailed—these practitioners were continually laying themselves open to an action at law for malpractice or, worse still, they ran the risk of being placed in the dock for manslaughter. The speaker estimated the true mortality of acute intestinal obstruction as nearer 60 per cent. than the figure usually given (35–40 per cent.)—an alarming state of affairs. It was a mystery to him, he said, that general practitioners and physicians, all of whom had come to recognise that the only satisfactory treatment for all other acute intra-abdominal conditions was early surgical interference, could not come to the same conclusion with regard to acute intestinal obstruction. Apart from acute intussusception, the speaker recognised three stages of obstruction: (1) Where (within 24 hours of onset) the patient's general condition was good and there was little or no distension; (2) where (within the second, third, or fourth day) the patient's general condition was still good, but there was considerable distension and the vomiting was severe; and (3) where the general condition was bad: pulse feeble, vomiting continuous and stercoraceous, abdomen distended, and the patient profoundly poisoned. Treatment in the first stage consisted in washing out the stomach with sodium bicarbonate solution and free opening of the abdomen under a general anæsthetic. When the obstruction had been dealt with the stomach was again washed out. In the second stage, the obstruction was similarly dealt with and removed, but, in addition to this, a separate incision was made through the left rectus above the umbilicus and a high loop of jejunum was brought out. A tube of 7 or 8 mm. diameter was fastened into this, after the method of Senn's gastrostomy, and by means of which the jejunum was drained and irrigated with sodium bicarbonate solution. Later the patient might be supplied with sodium bicarbonate and glucose by the same means. In the third stage, Sir William Taylor advised local infiltration of the abdominal wall and withdrawal of a loop of jejunum as above. Should the patient survive, the obstruction might be dealt with later. The washing out of the stomach in these cases is of paramount importance. In obstruction of the large bowel, cæcostomy after the manner of Sir Harold Stiles gave the best results so far as tiding the patient over his immediate dangers was concerned. The speaker then dealt with the condition of acute intussusception, and stated that in his practice it was the most common cause of acute intestinal obstruction. In these cases there could be no excuse for failing to make a diagnosis. He himself had had a total of 81 cases with only three deaths. In cases of obstruction of the adynamic type, Mr. Sampson Handley's method left little to be said on the subject, but Sir William Taylor was of opinion that in very severe cases jejunostomy with siphonage and gastric lavage, combined with morphia, might help the patient for a few days. Finally, he said, until physicians and general practitioners realised that there was only one legitimate treatment for acute intestinal obstruction—namely, early operation—we could not hope to improve our results.

Mr. Sampson Handley considered that the high mortality in obstruction cases was, at least in part, due to the fact that these operations were frequently done by medical men whose skill and training did not justify them in undertaking such a serious responsibility. He also blamed the authors of surgical text-books, whose description of the signs and symptoms of acute intestinal obstruction was often lamentably vague and confused. Mr. Handley insisted on the great value of the "two-enema" test—on the failure of the second enema the diagnosis might be considered as settled. He then dealt at length with the operation of precautionary lateral anastomosis and illustrated his points with diagrams. Death in general peritonitis was usually due to obstruction and not to the peritonitis as such, and the speaker believed that the recovery-rate, even in cases after obstruction had supervened, amounted to 75 per cent., if treatment was prompt.

Prof. D. P. D. Wilkie (Edinburgh) considered that the drainage and washing out of upper coils of intestine in late cases was of the utmost importance. He differentiated various forms of acute intestinal obstruction—such as the "closed-loop" obstruction and the "strangulation" type with its severe degree of shock. In cases of carcinoma causing obstruction, drainage of the bowel above without treating the carcinoma in the first instance was indicated. He considered that in old people with obstruction, the operation of bringing the loop outside, leaving it outside, and then excising it later, was a good one. He referred to operations for the drainage of the lymphatic system and emphasised the great importance of giving enormous quantities of fluid to patients with obstruction, as the chloride deficiency was made good by the fluid.

Mr. Ernest Cowell dealt with cases of acute intestinal obstruction occurring in elderly people and due to causes other than carcinoma. He summarised the notes of nine cases that he had met with and insisted on the importance of the early admission of doubtful cases for treatment.

Mr. Rowlands reported the statistics from Guy's Hospital for the years 1920–24. He considered that some deaths were undoubtedly due to errors of technique, and that though in early cases the operations were easy, in late cases they were very difficult. He believed in jejunostomy with drainage and siphonage in the late cases, and was of opinion that in cases of carcinoma a rapid examination of the abdomen should be carried out at the time of the drainage operation.

Mr. Max Page presented the statistics from St. Thomas's Hospital for the years 1920–24. He also showed a set of charts, comparing in a most interesting way the results of operations in 1900 to 1910.

Colonel Primrose (Toronto) spoke briefly of the operation for drainage of the lymphatic system. He considered the administration of sodium chloride intravenously as of great value in severe cases. Where the efficiency of the ileo-cæcal valve was destroyed, the seriousness of the prognosis, he said, was much increased.

Mr. Reginald Vick presented the statistics from St. Bartholomew's Hospital for the years 1920–24. He pointed out that the doctor was so often sent for only in the late stages, and that this was due to the disappearance of all pain, when gangrene had set in. He advocated the system of observation beds to which patients could be admitted before the *diagnosis* was certain, and described the working of this system at St. Bartholomew's Hospital.

Mr. Grey Turner presented the statistics from Newcastle Infirmary. The mortality for the radical cure of external hernia was ½ per cent.; for the cases with strangulation it was 20 per cent. The moral, he said, was obvious. He had seen little improvement in results in cases where toxæmia was established. Mr. Turner emphasised the fact that, in his opinion, fæcal vomiting was not a sign of intestinal obstruction but of impending death. He believed in the enema test and the calomel test, consisting in small doses of calomel at short intervals, the administration of which would either relieve the condition or complete the picture. The education of the public had its dangers, but he thought that the circulation of leaflets giving the considered opinions of experts might well be circulated to the profession.

Mr. Burgess said he did not see how Sir William Taylor could claim that he was called in late to cases of acute intestinal obstruction and yet was able to show a series of 81 cases of intussusception with only three deaths. He considered distension to be a most valuable early sign of intestinal obstruction, and that it was very important to distinguish, as far as possible before operation, between obstruction *in the large* and the small intestine. Blind cæcostomy was indicated in cases with obstruction due to malignant disease. The speaker also drew attention to the very high mortality in cases due to obstruction by gall-stones, and asserted that, in some cases, the obstruction *was undoubtedly due to the presence of two* stones, one of which was missed.

Mr. Souttar presented the statistics of intestinal obstruction for the years 1920–24 for seven hospitals. The total was 3064. He dealt at some length with the various points and demonstrated them by means of graphs. The very great frequency of intussusception as a cause of intestinal obstruction—second only to femoral hernia—was shown, and its incidence was almost entirely in the first year of life. The analysis of the mortality among the 3064 cases was as follows:—

Cause of obstruction.	Per cent.	Cause of obstruction.	Per cent.
Gall-stones	60·0	Intussusception with tumour	35·0
Carcinoma	43·5	Volvulus	61·0
Adhesions . ..	31·0	Inguinal hernia ..	10·0
Internal strangulation	33·0	Femoral hernia ..	20·0
Intussusception (idiopathic)	22·0	Umbilical hernia ..	35·0

Reply.

The *President* briefly replied, and stated that his good results in cases of intussusception were undoubtedly due to the fact that he had preached its signs, symptoms, and treatment at all times and in all places. He said that he was prepared to bear any amount of censure for *his* opening remarks, provided that they secured the result he aimed at—namely, the early operation in all cases of acute intestinal obstruction.

JOINT MEETING OF THE SECTIONS OF SURGERY AND ORTHOPÆDICS.

FRIDAY, JULY 24TH.

TREATMENT OF FRACTURES.

AT the joint meeting of these sections a discussion was held upon the treatment of fractures with special reference to its organisation and teaching. The Presidents of the two Sections, Sir Berkeley Moynihan (Surgery) and Prof. E. W. Hey Groves (Orthopædics), occupied the chair in the earlier and later parts of the meeting respectively.

Prof. G. E. Gask (London) held that although the plan of the segregation of fractures in special wards and under a *special staff*, advocated by Sir Robert Jones, might be of service to an occasional individual patient, it would involve such great difficulties in a teaching hospital that a change from the present organisation was not advisable. He professed himself *opposed to the growing tide of specialism which first* began when surgery was divorced from medicine by an edict of Pope Alexander III. in 1163. He shared the view of the late Sir Clifford Allbutt that this artificial separation of the two great branches of the healing art was the greatest blow that *had befallen* the profession and still constituted a weakness. Any further separation was to be deprecated and our efforts should rather be towards fusion. While it was obvious that those who specialised in a small subject could and did attain a higher degree of skill in that branch and had been the authors of many advances, such an argument could not be applied to the education of medical students, whose chief need was a firm grounding of the fundamental principles which were applicable to all types of injury and disease. The present medical curriculum was overloaded with special subjects, such as diseases of the eye; of the ear, nose, and throat; lunacy; fevers, and so forth; and there was a danger that in the desire to teach a smattering of everything the main principles of medicine would be forgotten. His own hospital recognised this danger when, after long discussion, they decided not to establish a separate department of urology. Certain of the younger members of the staff were, however, encouraged to take up and teach *this specialty in conjunction with their ordinary* work as general surgeons. Thus the student was enabled to start his professional work with the knowledge that there was no mystery about the use of the cystoscope and that with practice he might attain sufficient skill in handling it to make it a valuable addition to his armament as a general practitioner. Sir Robert Jones's recommendation, if carried into effect, would establish a fresh department and still further subdivide the student's education. It was his belief that any defects in the treatment of fractures at the great centres of medical education would speedily be remedied without recourse to such a step. Medical schools were very sensitive to public opinion, and the fact that it had been thought necessary to hold such a discussion and the publicity given to it would, in itself, be sufficient to stimulate them to make any essential reforms in that branch of their work.

Sir Robert Jones (Liverpool) held that the treatment of fractures was not as good as it should be and that the great teaching hospitals should give a lead to better things. Fractures were regarded as an incubus in most of the general surgical wards; they were of little interest to the majority of general surgeons, whose house surgeons were encouraged to discharge them at the earliest possible moment to make room for patients who needed some form of operative treatment. And the treatment of out-patient fracture cases, which was left almost entirely to the inexpert resident staff without any supervision by the surgeons themselves, was even worse. One very frequently saw lamentable deformities, which should not have arisen, follow fractures treated at teaching hospitals. He maintained that the treatment of the patient should be the first consideration at all hospitals and that the training of medical students even at the teaching hospitals was a secondary matter, although he did not admit that the segregation of fractures, which he advocated, need involve any insuperable difficulty in medical education. The "segregation scheme" was already in successful operation in many teaching hospitals in America and in several in this country with marked benefit to the patients and no ill-effect upon medical education. The results which might be achieved by his scheme were illustrated by those obtained in the cases of fractured femur during the latter part of the war (when specially trained staffs were available) which were better than any ever attained before. The lesson which should have been learnt then was already being forgotten, and again one saw gross errors in the treatment of common fractures which arose, he thought, from lack of interest on the part of many of those who held the responsibility for treatment. His scheme of segregation of all fractures in one department, not necessarily under an orthopædic surgeon or indeed under any one surgeon, would lead to comparison of results and a healthy rivalry between those in charge, with resulting benefit to both patient and surgeon. Only those surgeons who took an interest in this work need participate in it, and others would be glad to be relieved of the responsibility and freer to carry on the work in which they were more especially concerned.

Mr. S. W. Daw gave details of the working of a special fracture department under his charge at Leeds. He emphasised the teaching value of a resident orthopædic officer working under the general or orthopædic surgeons. This officer did a daily teaching round and gave demonstrations of details of splintage and the many items that needed daily supervision in a manner that the heads of departments had neither the time nor the patience to do.

Dr. R. Osgood (Boston, Mass., U.S.A.) said that a scheme of the type advocated by Sir Robert Jones had been in operation in his hospital for some years. Prior to this some fractures—in particular the not uncommon compression fracture of the spine—were not recognised, and others had resulted in unnecessary crippling of patients. As a result the great industrial concerns had been forced to form their own fracture clinics and this had stimulated the medical profession in America to take a greater interest in fractures. At a conference between surgeons from all parts of the United States a syllabus of standardised treatment of fractures was agreed upon and published. Dr. Osgood gave details of the intensive teaching of students, at the fracture service, which appeared to be very thorough.

Mr. Henry Wade (Edinburgh) commented upon the general agreement that the treatment of fractures was at present unsatisfactory, and pointed out the heavy financial cost of failures to the employer of labour. One employer had told him that a case of malunited fracture of the femur cost from £500 to £1000. No argument as to the interests of the medical student was admissible when those of the patient were compromised by the present system. But in point of fact segregation gave opportunities for that hour-to-hour teaching by a whole-time officer which was so necessary in this special department.

Mr. H. Platt (Manchester) had had charge of a fracture service for 12 years, during which 40 residents had passed through the department, the majority of whom were now in general practice. These men were able to deal with fractures in their own practices with confidence and ability.

Mr. H. A. T. Fairbank (London) had charge of a fracture service and found that it possessed many advantages from the teaching point of view, since in one hour many types of fracture could be seen and demonstrated, and the apparatus used could be standardised so as to combine simplicity with efficiency. He admitted, however, the difficulty of getting the student to attend a fresh department, and suggested a revision of the curriculum to enable more time to be devoted to this important branch.

Mr. H. H. Sampson (Birmingham) was averse to segregation from the teaching point of view. He pointed out that to be efficient the fracture service would have to be a night-and-day one, since the ultimate result depended largely on the officer (usually the casualty house surgeon) who first saw the case and splinted it. Should a separate department be established the problem of the allocation of the student's time, already overburdened, would be reopened, and, finally, the ordinary house surgeon would lose the benefit of having handled these cases which were so instructive to him in general practice later.

Mr. Max Page (London) did not approve of the creation of a new specialty. For the general practitioner in the country and for the doctors in the services and abroad it was essential that instruction in the treatment of fractures should be a part of the ordinary surgical curriculum, and not regarded as a specialist's department. If segregation were adopted it must fulfil this condition.

Prof. A. W. Sheen (Cardiff) was also averse to making a new specialty. He pointed out that in many emergency conditions, particularly those arising from motor accidents, the fractures played but a small part in the condition, which might call for the excision of wounds, blood transfusion, and other measures directed against shock which would not come within the province of a fracture specialist. He advocated instead the establishment at the teaching hospitals of one or more large surgical teams which should include one member with a special training in fracture work as well as experts in other departments. He agreed, however, on the advisability of establishing a special fracture out-patient department. The student could not be expected to become expert or even familiar with all fractures, but should have his teaching concentrated upon the commoner ones. A "follow-up" of fracture cases showed that many results were much worse than they should be.

Mr. Gwynne Williams (London) remarked that the active treatment of a fracture only ceased when the patient was restored to full activity, whereas, for example, in the average case of appendicitis the treatment was practically concluded at the operation. For this reason he made one student responsible for each fracture case, who should as far as possible see the case through to a conclusion. It was very important that if any change was to be made the ordinary residents should still have opportunities of handling fracture cases.

Mr. McAdam Eccles (London) was against segregation, mainly because of the difficulties it would involve in teaching. To establish a fracture ward would also entail a large increase in beds devoted to this service with a consequent reduction of those available for general surgical work. Already the establishment of separate departments for venereal disease and tuberculosis had resulted in a reduction of the opportunities afforded the student of studying these cases. He maintained that the present system at St. Bartholomew's, while not the ideal one for every fracture case, was the best possible in the long run for the average fracture.

Mr. R. C. Elmslie (London) pointed out that over 100 years ago St. Bartholomew's Hospital had appointed two surgeons specially to deal with fractures, although the office had been allowed to lapse. He complained of the lack of proportion in the allotment of the student's time, and that much of it was wasted in watching operations and writing them up which might more usefully be employed in learning more of the subject under discussion. A fracture ward, the beds of which were open to all the surgeons, would promote rivalry while leading to *standardisation of apparatus so that the student* might have a clear-cut picture of one treatment for each fracture instead of a confused picture of many. It would be easy to arrange space in the student's curriculum (at least at his own hospital) to carry out the reform.

Prof. A. Fullerton (Belfast) did not consider a separate fracture service necessary at his hospital. Though his beds were limited he never refused a fracture case and devoted much time to them with gratifying results. His house surgeons, who were taught to regard shortening of one inch or a stiff knee after fracture of the femur as a disgrace, shared his enthusiasm. As a result, the average shortening in his last 40 cases of fracture of the shaft of the femur was under one-quarter of an inch. Many fractures must of necessity be treated in small cottage hospitals or even in their own homes by ex-dressers; he therefore felt that it was important that instruction in fractures *should be a part of* the student's general surgical training and not handed over to a special department.

Mr. W. R. Bristow (London) urged that the example of gynæcology, with its separate staff, residents, nurses, and wards, proved that teaching need not suffer by the establishment of a separate department. He supported the suggestion that the student's time-table should be reorganised, and maintained that the proper teaching of fractures could only be obtained by segregation.

Mr. R. C. Affleck made a plea for greater simplicity. The late Prof. Lucas-Championnière was not ashamed to exhibit to the world the results he was able to attain without any apparatus at all. The speaker maintained that the proper place to treat any fracture was in the nearest bed. He had recently been in an operating theatre where fractures were treated, and a list of the instruments kept there contained over 1000 items.

Dr. A. T. Bazin (Montreal) said that at his hospital there was a fracture department under his charge, but not all fractures came to the department. In over 2000 cases they had no case where amputation had to be performed, although one or two came into the department with a recent amputation. There were three cases of delayed union, no cases of non-union, and no operations for plating were performed; but three plates were removed from cases transferred from elsewhere. It was acknowledged that the results obtained in the fracture clinic were better than those of the general surgical wards in the same hospital. Students received tuition in the clinic and, indeed, the teaching had proved so successful that they were now asked to extend their work in that direction.

Prof. Hey Groves remarked, from the chair, on the virtual unanimity of all the speakers that there was room for improvement in the present treatment of fractures in general surgical wards. War experience had made us unsatisfied with present results. It should not be thought that the discussion exhibited a gulf between the general and the orthopædic surgeons; Major M. Sinclair's work in connexion with fractures of the femur was sufficient to show what could be done by the general surgeon in the treatment of fractures when his interest was stimulated.

SECTION OF ORTHOPÆDICS.

THURSDAY, JULY 23RD.

TUBERCULOUS DISEASE OF THE SPINE.

Under the presidency of Prof. E. W. Hey Groves (Bristol), Sir Henry Gauvain, in the unavoidable absence of Dr. J. Calvé (Berck), opened a discussion on this subject. He commented on the great improvement in the treatment of Pott's disease which had taken place during the last 20 years. The severe deformities—so common years ago—were now comparatively rare. Bacteriological investigations conducted by Dr. Stanley Griffith (Cambridge) suggested that the number of cases of Pott's disease due to the bovine bacillus was on the increase, so that the *problem was intimately concerned with the* campaign for the provision of a pure milk-supply. In the therapeutics of this condition the value of general measures and adjuvant treatment, such as heliotherapy and artificial light, was universally accepted. He believed that the general mortality of Pott's disease had been reduced considerably by the introduction and adoption of the aspiration of abscesses. Calvé's intraspinal tapping of an abscess producing paraplegia was a valuable addition to our treatment methods. With Calvé and others the speaker deprecated the performance of any of the ankylosing operations—e.g., Albee bone-graft or Hibbs's operation—in children. In the adult, however, such operations were founded on sound principles. The mechanical methods used at the Treloar Hospital, Alton, were next described and illustrated by lantern slides.

Mr. G. R. Girdleston (Oxford) believed that the ankylosing o*perations had a certain rôle in the* treatment of children with Pott's disease. It was not unusual to find that the deformity increased in ambulatory patients who had had efficient early treatment. In such cases a spinal fusion was an added safeguard. The technique he adopted was that of Hibbs, with the addition of osteo-periosteal grafts laid on each side of the spinous processes. The problem of Pott's disease in the adult was much more formidable, and especially where sinuses had developed. In his own hospital out of a consecutive series of 80 adult cases, 9 were admitted with sinuses—of the latter, 8 died after varying periods. Mr. Girdlestone advocated very free operative drainage in all such infected cases.

Dr. W. T. Pugh (Carshalton) declared himself as an uncompromising opponent of spinal fusion operations in children. He emphasised the potential dangers of hyperextending the spine at the level *of the disease during the period of recumbency on* a frame. He chose a suitable level of the spine at which to produce a compensatory lordosis, and hyperextended the frame accordingly. It was necessary in the ambulatory stage to use a jacket which controlled the spine and allowed for growth; otherwise late deformity would develop.

Mr. D. McCrae Aitken (London) said he was in favour of complete and uninterrupted immobilisation during the stage of recumbency. He carried out spinal fusion by operation almost as a routine, but with no neglect of adequate splinting. The operation was not suitable for young children and should only be performed after deformity had been corrected. It was especially successful in the cervical and lumbar regions.

Mr. F. C. Pybus (Newcastle) emphasised the necessity for a prolonged period of after-care. The criteria of cure were not easy to define although valuable information was gained from a scrutiny of successive radiograms. In his hands the treatment of cold abscesses by open evacuation with careful sponging and subsequent closure had given excellent results.

Mr. S. Alwyn Smith (Cardiff) condemned wholeheartedly open operations for cold abscesses. He deprecated the tendency to cut down the period of recumbency.

Mr. R. C. Elmslie (London) referred to his surveys of crippled children in the London County Council schools, which had shown in a most striking manner the value of the provision of country hospitals. He did not consider that it was always advisable to attempt to correct an established kyphus; in any case correction was apparent only and was gained by providing compensatory curves. In his opinion the ankylosing operations had come to stay. He operated on patients over the age of 14 years at a stage when the disease was becoming quiescent. Adequate post-operative treatment was, of course, an essential.

Mr. H. A. T. Fairbank (London) dealt with the difficulties in diagnosis. Developmental anomalies of the spine and new growths might simulate Pott's disease. A number of radiograms illustrating such cases were exhibited. He practised spinal fusion operations in patients over 14 years, and he believed it was better to ankylose a less limited area of the spine than was generally taught. He had met with a few cases where there were two foci of spinal disease at different levels. He agreed with Mr. Girdlestone that very free drainage should be established in all sinus cases.

Mr. T. P. McMurray (Liverpool) considered that patients with sinuses did much better when allowed to walk about wearing a suitable spinal brace. In his opinion the ankylosing operations should be reserved for adults.

Prof. R. B. Osgood (Boston) quoted his impression of Scandinavian clinics, which he had recently visited, and said that one was bound to recognise that with what might be termed partial immobilisation very perfect results were obtained. The findings of the Commission of the American Orthopædic Association on the value of the spinal fusion operations were quoted—namely, that such operations did not, in themselves, control the advance of the disease or deformity. In his own clinic an operation of the Hibbs's type combined with osteo-periosteal "ribbon" grafts was practised; he did not consider the Hibbs's operation as inherently difficult. In adult patients it was evident that multiple foci of disease at different levels were not infrequently seen. Difficulty in diagnosis arose and, in adults, in the early stages syphilis, malignant disease, and multiple myelomatosis must always be borne in mind.

Mr. S. W. Daw (Leeds) thought it was wise to avoid too great a degree of hyperextension of the spine during the recumbency stage. He had experienced very good results from spinal fusion, but he did not do the operation in children.

Dr. T. Hartley Martin (Leasowe) had employed Calvé's method of intraspinal aspiration in a number of cases, and he did not think the method had any special dangers. It was not difficult if one practised first on the cadaver. It must be recognised that relief from paraplegic symptoms could only follow in cases where the compression was due to the presence of an abscess sufficiently liquid to be tapped.

Sir William de Courcy Wheeler regarded the operation of spinal fusion as a valuable addition to recognised conservative methods. His method was to implant a graft on the rawed surfaces of the laminæ.

The discussion closed with the reply of Sir Henry Gauvain.

OSGOOD-SCHLATTER DISEASE.

Mr. R. Ollerenshaw (Manchester), in a short paper illustrated by radiograms, presented an analysis of 32 cases he had dealt with personally. He considered that in childhood two lesions occurred consequent upon sudden traction on the lower quadriceps mechanism, (*a*) a traction-fracture of the tip of the upper tibial epiphysis (Osgood-Schlatter disease), or (*b*) a fracture of the lower end of the patella. In three cases where both knees were simultaneously injured one side showed the first type of lesion and the other the second type. Both types were therefore representative of the common fractures of the patella in adults. The treatment advised was complete immobilisation for one month, followed by a period of six weeks, during which the range of knee flexion was restricted.

Prof. Osgood referred to the effects of traction by such a strong tendon on an actively growing epiphysis. He agreed that although the earlier cases he described had all occurred in boys, it had since been found that girls were equally liable. In some cases it was possible to obtain a cure by simple strapping down of the patella.

SECTION OF DISEASES OF CHILDREN.

THURSDAY, JULY 23RD.

Treatment of Empyema.

Dr. Carey F. Coombs, who presided in the absence of Dr. Robert Hutchison, said that the subject of empyema had made considerable progress of recent years, but it was time that we discovered the effect of war surgery on its treatment; whether, for instance, primary suture had been found to answer in civil life. An increased sense of responsibility towards cases of empyema had arisen in the medical profession. It was no longer regarded as something to be dealt with by telling the house physician to make an incision. Its treatment required the coöperation of physician and surgeon.

Dr. Hector C. Cameron, in opening the discussion, confined himself to the medical aspects of empyema. In infants the condition had a very high mortality: 75 per cent. in the first year and 50 per cent. in the second year of life. In the third year the figure dropped to 18 per cent. and thereafter remained at about 6 per cent. The high mortality of the first two years of life was due to the long duration of pneumonia at that age. It was always a favourable feature when the rise of temperature due to the pneumonia was separated from that due to the empyema by an interval of time (metapneumonic empyema). If the empyema developed when the pneumonic condition was still active (synpneumonic empyema) the prognosis was not so good. Empyema in young children was generally synpneumonic owing to the duration of the attack of pneumonia. In the third year of life the short-lived lobar type of pneumonia became the rule, and empyema was of the metapneumonic type with corresponding improvement in the prognosis. Among adults and older children synpneumonic empyema hardly ever occurred except with influenzal pneumonia. The distinction between synpneumonic and metapneumonic empyema was important from the point of view of treatment. Rib resection was apt to be fatal in the former type though followed with most satisfactory results in the latter. The best results in synpneumonic empyema were obtained by aspirating the pus until the lung condition had improved, when an operation might be performed. But successful treatment was not concerned merely with saving life. It was necessary to restore the function of the lung. Expansion of the lung was most often prevented by thickened pleura and the formation of fibrous tissue around the cavity. This result was due to delay in the establishment of satisfactory drainage, insufficient drainage, or to secondary infection, presence of a bronchial or pulmonary fistula, or of a foreign body in the cavity. Early diagnosis and operation at the right moment were of the greatest importance in preventing chronic empyema. Once the lung was bound down by rigid fibrous tissue decortication alone would release it.

Mr. Henry S. Souttar analysed the cases treated in the London Hospital for the last 15 years. Half the cases occurred under the age of 10, and 70 per cent.

of these were between the ages of 1 and 6. The mortality was highest in the first year, 73 per cent., but the number of cases was small. In the second, third, and fourth years the number of cases was larger and the death-rate was from 40 to 60 per cent. The mode of onset was important in prognosis and treatment. When empyema occurred as one feature of a general infection it was often fatal, and any attempt at radical treatment would lead to disaster. When it followed a subsiding pneumonia operation was indicated and the outlook was good. Probably empyema of itself was never fatal. Death was due to accompanying disease of which empyema was only a particular manifestation. The type of infecting organism was important. The mortality in pneumococcal infection was 6 per cent., in streptococcal 24 per cent. In pneumococcal empyema massive adhesions formed, limiting the disease and preventing gross collapse of the lung. Ultimately the adhesions might delay recovery and lead to chronic empyema, but in the acute stage they were of service. In this type the best treatment was to open the cavity freely, evacuate the pus, clear out all solid masses of fibrin, and drain the cavity by a closed method. In young children an intercostal incision would give sufficient access, but in older children rib resection was more satisfactory. The pus must be evacuated slowly.

In the non-adherent form of empyema repeated aspiration was indicated for perhaps five or six days. The form of operation then undertaken would depend on the patient's condition. The post-operative treatment was most important. Sterilisation of the cavity and expansion of the lung were the objects to be achieved. Siphon drainage, and in some cases injection of saline or Dakin's solution, were the best means to this end. Local anæsthesia was contraindicated in children. Ether or chloroform might be used, but the speaker preferred gas and oxygen as an anæsthetic for this operation.

Dr. F. G. Chandler, from the point of view of treatment, classified empyema into four groups: Ordinary (occurring after or during pneumonia), acute fulminating, chronic, and tuberculous. Rib resection was introduced by Arbuthnot Lane in 1882, and as a result mortality diminished considerably. At the same time our conceptions of disease were advancing and the importance of early diagnosis was being recognised. It was wrong, however, to employ rib resection as a routine in young children. Under the age of 4 it should never be necessary. He had seen cases end disastrously which might have been saved if preliminary aspiration or treatment by simple incision and drainage had been employed instead of resection. In the treatment of empyema four things had to be considered: The evacuation of pus, the expansion of the lung, the speediest convalescence, and the comfort of the patient. Suction drainage had been employed to bring about expansion of the lung, but in the speaker's opinion this was tackling the problem from the wrong aspect. If the lung did not expand it was because there was disease within it or because it was held prisoner by thickened pleura and adhesions. The latter could be dealt with mechanically or by irrigation with Dakin's solution. Fulminating empyema was usually due to a streptococcal infection. The only treatment was repeated gentle aspiration until the patient could support operation. It was important to aspirate slowly, replacing the fluid with air if the patient showed signs of cyanosis or collapse.

Mr. W. H. C. Romanis, while agreeing cordially with those speakers who laid stress on the mortality of empyema in young children, wished to call attention to the serious sequelæ of sinus formation, fibrosis of the lung, and bronchiectasis in patients who recovered. Surgically speaking, there were four chief kinds of empyema: those due to the pneumococcus, those due to the streptococcus and other organisms, those which were early, and those which were late. It was of the greatest importance to ascertain the nature of the organism before operation. The masses of fibrin formed in pneumococcal empyema often caused an alteration in the physical signs. In adults it was essential to remove the fibrin at operation as it would interfere with the healing of the wound and the expansion of the lung. But in children, although removal of solid masses of fibrin was important, everything had to be done to minimise shock, and therefore repeated aspiration should be tried before resorting to operation. There was no urgency about operating in pneumococcal empyema, in contradistinction to the streptococcal variety, in which some method of removing the pus should be proceeded with immediately. Aspiration might be practised at first; but if the patient did not improve in a day or two either operation or the insertion of a large cannula must be resorted to.

Mr. T. Twistington Higgins said he had no panacea to bring forward. Success in dealing with empyema depended on early and accurate diagnosis and efficient operative and post-operative treatment. The operative procedure employed would depend on the age and condition of the child, the character of the pus, and the size of the empyema. In his experience a knowledge of the bacteriology of the pus did not assist much in treatment. He had not found it possible to say that all pneumococcal cases should be opened and all streptococcal cases aspirated. Some indications of the patient's resistance might be obtained from noting the characters of the white cells and the extent of phagocytosis exhibited by them. Dr. Hugh Thursfield was endeavouring in this way to sort out cases which might have the chest wall closed after evacuation of the cavity. The closed system of drainage was best. Continuous aspiration was useful in some cases and could be carried out by the method of Poynton and Reynolds. Breathing exercises were of great benefit in promoting re-expansion of the lung.

Dr. Clarke gave his experience of primary closure in empyema. The type of case suitable for primary closure was the chronic case which gave so much trouble when dealt with by other methods. Out of 21 cases two healed by first intention. In the others the wound broke down, but all did well. Primary suture was worth trying because, even if the wound broke down, the patient was no worse off than if a tube had been inserted in the first place.

Dr. L. A. Parry said that happily there was agreement between the speakers on main points. He thought, however, that a piece of rib should be excised in all cases even in young children, though not more than 1 in. to 1½ in. was necessary. The game of soap-bubbles was excellent as an exercise for re-expansion of the lung.

Mr. R. A. Ramsay considered that the objection to rib resection in young children was that it made the operation longer and more severe. In infants all operative measures should be reduced to the shortest time. The difficulty that the incision was not large enough could be overcome by using two moderate-sized tubes side by side. After 24 hours a large tube could generally be inserted. When pus was evacuated from an empyema the diaphragm rose and the chest wall tended to fall in, thus obliterating the lower part of the cavity. It was therefore necessary to drain not at the lowest but at the highest point of the abscess. As the patient was in bed drainage would be equally efficient.

Dr. Wilkie Scott pointed out the difficulties encountered in dealing with very chronic cases of empyema. He raised the question whether in such cases it was not best to aspirate or to close the cavity by primary suture.

Mr. P. T. Crymble agreed with Mr. Ramsay that the incision should be made in the region of the fourth rib. He found treatment of chronic empyema most unsatisfactory. The cases relapsed constantly. Decortication was a dangerous operation.

Reply.

Dr. Cameron said in reply that the discussion clearly showed that in the details of surgical procedure—the site and the extent of the incision, the character of the drainage, and so forth—there was very great divergence of opinion. It seemed to him that the prognosis was mainly determined by one consideration only, whether or not intervention was made at the right moment. He thought the same was true in pneumococcal peritonitis. The evacuation of a residual collection of pus gave brilliant results. The high mortality of pneumonia in young children limited the opportunities of securing this result.

Mr. Romanis replied for Mr. Souttar. He said that the details of technique had been thoroughly discussed. Primary closure was not an unreasonable procedure in adults, but it was open to objection in children. Resection of a rib added to the gravity of the operation in young children. A rib-spreader was necessary for exploration, for with it good access could be obtained. He agreed with the speakers who advocated high incision.

In our issue of August 8th, p. 286, in reference to the display at the exhibition at Bath, we alluded to the drugs S.U.P. 36 and S.U.M. 36, prepared by the British Dyestuffs Corporation, Ltd., as arseno-benzene preparations. We are informed by the Fine Chemicals Department of the Company that these products contain no arsenic in the molecule, and we are happy to correct the erroneous impression given by the note.

Reviews and Notices of Books.

MALARIA INOCULATION IN G.P.I.

Die Malariabehandlung der Progressiven Paralyse. By Dr. JOSEPH GERSTMANN. With a Foreword by Prof. J. WAGNER-JAUREGG. 1925. Pp. 229. G.M.12.

THE treatment of general paralysis of the insane by means of the inoculation of malaria has recently aroused considerable interest. This empirical method has been used in many countries during the last few years, and this book is a detailed account of its history and technique, and of the results obtained both by its pioneers and those who have followed them. We will not trace here the very interesting story in detail, but will leave that for readers of the book. It is sufficient to say now that, for some reason unknown, a succession of any febrile attacks will apparently counteract the disease; and the malarial excitant is chosen because it is very safe, is easily controlled with quinine, and is not communicable even by the anopheles mosquito. The account of the experiments which have established this last fact forms one of the most interesting side-issues in the book.

The author takes blood from an approved tertian malarial patient who has not had quinine and injects subcutaneously 1 c.cm. into the back, pricking deeply and distributing the injection over the different skin layers. The blood should come direct from the donor without delay. The incubation period is from 4 to 8 days normally and can be shortened by using intravenous instead of subcutaneous injection, but this is not recommended. Attacks of fever then proceed at regular intervals, and after 8 to 12, according to the condition of the patient, they are stopped with quinine, of which the usual dose is 8 gr. of the bisulphate twice a day for three days and then once a day for the next four. The exact dose is varied to suit the individual. The condition of the cardiovascular system is ascertained before injection, but the risk of the treatment is slight. Ten minims of the tr. strophanthus are given at the height of each malarial attack, and digitalis may be used throughout if the heart is weak. Treatment must be interrupted for a sudden drop in strength or for alarming heart or gastric symptoms, but not for anæmia or jaundice unless the anæmia be pernicious in type. If necessary, a small dose of quinine will hold up the fever for a few days, and 10 c.cm. of a 10 per cent. solution of sodium nucleinate given intravenously will restart it.

The indications depend on the age and general condition of the patient and on the form and duration of the paresis. The pyrexia is not dangerous, but if it be interrupted too soon the paresis is not affected. The author places the age-limit between 9 and 68 years, and his oldest case (of 62) is still enjoying a complete remission. Any patient of average strength and stamina can be treated, and aortitis in syphilitics does not counter-indicate treatment unless there is an aneurysm or evidence of myocardial degeneration. Active tuberculosis of the lungs has not been stimulated in the cases under the author's care, though others have reported to the contrary, while healed tubercle has never been lit up. The patient must be quinine-tolerant and not resistant, but quinine idiosyncrasy is a rare thing. The treatment is not suitable for private practice and should not be used in institutions unless the malarial infection is properly understood. Dr. Wagner-Jauregg once lost three patients out of four through the error of a military hospital in sending him a culture of malaria which was not tertian.

Dr. Gerstmann gives a very full statement of the results obtained both in the university clinic where he works in Vienna and in other institutions. He defines a "full" remission as a return to full working efficiency with a disappearance of all but the slightest psychic symptoms, and a "partial" remission as either good or slight. "Good" is a return to social life and light work, and "slight" is a slackening of acute symptoms with improvement enough to allow the patient to return home. Out of 1000 cases only 400 are quoted who have been kept under observation for two years, and of these 33 per cent. show lasting and complete remissions; 14 to 25 per cent. show good partial remissions, while the proportion of cases in which there has been minor improvement with arrest of the disease amounts to about 30 per cent. The symptomatic improvement was in many cases followed by a return to a negative Wassermann reaction in the cerebro-spinal fluid and a disappearance of cells, though the globulin reaction tended to persist. The simple dementing and maniacal forms of paresis are the most amenable to treatment, next come the periodic, and then the tabo-paretic varieties. The best prospects are afforded, naturally, where the condition is caught at an early stage. The method has been tried, but without success, in non-syphilitic paralyses.

Dr. Wagner-Jauregg and Dr. Gerstmann are still busy with the research which they hope will issue in establishing the malarial treatment as a specific remedy. Their book is extremely comprehensive and well arranged, and contains several good microphotographs of brain tissue. Every angle of the subject is explored and discussed with thoroughness, and although the language is quite intelligible even to a moderate German scholar, it will be a great pity if an English translation is not published at once.

TREATMENT OF INTERSTITIAL KERATITIS.

A Preliminary Report. By R. LINDSAY REA, M.D., F.R.C.S., Ophthalmic Surgeon to West End Hospital for Nervous Diseases; Assistant Surgeon to Western Ophthalmic Hospital. London: H. K. Lewis. 1925. With three plates. Pp. 32. 2*s.* 6*d.*

THIS is a paper that was recently read before the Ophthalmological Section of the Royal Society of Medicine and covers much the same ground as an address on the same subject read by the author at the Bath meeting of the British Medical Association this year. Its interest lies first in relation to the diagnosis. The author apparently does not believe that any typical case of interstitial keratitis is non-syphilitic. Recent cases give a positive reaction to the Wassermann test, while those old cases which do not still give evidence of syphilis by a positive luetic curve with Lange's colloid gold test. Such has been Mr. Rea's experience, which is very different from that of some other authors, who attribute from 10 to 30 per cent. of the cases to tuberculosis. The other main point in this essay is the importance attributed to active treatment, and especially to arsenical injections—preferably of novarsenobillon. Tables are appended contrasting the results of cases treated with those untreated, or treated only by atropin, or in which treatment was deferred till too late. There is a possible fallacy in this comparison in that the class of untreated or badly treated cases would naturally include many "chronics" who spend their lives in going from hospital to hospital without much material benefit. Allowing for this, however, the contrast is sufficiently striking.

This little volume is important in that it constitutes a definite challenge to those who still maintain that in interstitial keratitis the specific treatment for syphilis is of no effect. In Mr. Rea's view it is urgent.

BLOOD TRANSFUSION.

La Transfusion du Sang. Étude Biologique et Clinique. Par P. EMILE WEIL et PAUL ISCH-WALL. Paris: Masson et Cie. 1925. Pp. 247. Fr.20.

THE recent publication at Paris of a work on blood transfusion by Drs. Pauchet and Bécart has been followed after the lapse of only a few months by the appearance of a second work on the same subject by Drs. Emile Weil and Isch-Wall, which is the subject of the present review. Two books covering so nearly the same ground and published almost at the same time can only be regarded as rivals, and it may be stated at the outset that the book which is second in time of publication is easily first in merit. It is a book of greater authority than its predecessor, having been produced by two writers who have already made numerous contributions to the literature of transfusion, and shows evidence of a more thorough knowledge of the ramifications of the subject.

An interesting account of the history of transfusion is followed by chapters on the "biology" of transfusion in general and of citrated blood in particular. It is apparent from this section that the authors are convinced followers of the school of Lewisohn, and they advocate the use of citrated blood as opposed to the use of so-called "whole blood." They lay emphasis on the fact that citrated blood is to be regarded not as "modified blood," but as "stabilised blood," its general biological characters remaining unaltered. The calcium ions of the blood are inactivated by the addition of sodium citrate but are not destroyed, and are capable of regaining their activity when the citrate has been removed, as happens in the body of the recipient soon after the injection of the blood. Sodium citrate the authors believe also to be non-toxic in the quantities usually administered in the course of a transfusion.

Even at the present time surgeons can be found who regard the group reactions as being of theoretical interest but of no practical importance, this opinion being based on a happy immunity from "accidents" in performing transfusions with untested donors during the late war. It is instructive, therefore, to find in the present work an account of 12 transfusions performed by the authors before the group test had been introduced. Even in this short series of cases they experienced three serious "accidents," and no more conclusive evidence as to the practical importance of the test could be desired. First-hand information concerning these reactions is not usually found in works on transfusion, most writers having used only tested donors.

A section on the technique of transfusion is devoted largely to the description of a simple method of injecting citrated blood with a syringe as used by the authors. The employment of oxygenated blood described by Pauchet and Bécart is justly dismissed as a device which may satisfy the operator's complaisance without conferring any benefit on the patient. The authors claim, however, that the administration of forced oxygen through the patient's lungs during the transfusion is an additional measure of real value. The sections on the indications for transfusion are comprehensive, covering surgery, medicine, and obstetrics. The authors perhaps exaggerate the value of transfusion in the treatment of ruptured ectopic gestation when they state that some patients may be saved thereby from certain death. General experience goes to show that the hæmorrhage in this condition is seldom or never fatal, and that routine transfusion in treating it is unnecessary. Each chapter is provided with an adequate bibliography and there are a number of figures in the text.

The book may be recommended as an excellent and up-to-date monograph on an important subject. At the present rate of exchange it is very cheap.

THE EXTRA PHARMACOPŒIA.

Eighteenth edition. In two volumes. Vol. II. Revised by W. HARRISON MARTINDALE, Ph.Ch., F.C.S.; and W. WYNN WESTCOTT, M.B. Lond., D.P.H. Lond. London: H. K. Lewis and Co., Ltd. 1925. Pp. 728+xiii. 20s.

THIS volume constitutes an addendum to the first volume of the eighteenth edition, issued in October, 1924, but in many respects its compilation must have proved as strenuous a task as that of the main volume. The second volume provides a review of reviews (coupled with the authors' well-known laboratory notes) on analytical, experimental, and research work, covering with remarkable completeness the ever-multiplying specialities in these fields. The compilers are to be congratulated on their efforts in incorporating in this volume such very recent work as Gye and Barnard's researches on the filterable cancer virus, the use of the halogenised phenolphthalein compounds intravenously and per os as liver function tests and for gall-bladder visualisation, and induced malaria as a treatment for general paralysis. In the domain of chemistry a practically complete organic analysis chart, arranged in groups, is included, and an account is given of the investigations of flour and bread sold in London shops made as recently as May of this year. It is safe to say that there is no text-book at present on the market wherein these features are to be found. The chapter on radium and its congeners has been fully revised and several important alterations made in such factors as atomic weights, radio-active constants, &c., in the light of the 1923 International Table of Radio-active Elements. The (London) Radium Institute Reports up to 1925 are added.

In this volume the compilers have stolen a march on themselves by incorporating a good deal of material which they might have reserved for the next issue of Vol. I.; they are to be congratulated on their generosity, which has resulted in greatly enhancing the value of the present volume. Instances in point may be mentioned regarding treatment with organic antimony compounds, carbon tetrachloride, gentian violet, mercurochrome, and similar items which have lately been brought into prominence.

We trust that this invaluable work—indeed it is one of the few compilations that merit this adjective—will go on from strength to strength.

The death on July 30th of Dr. W. Wynn Westcott, an original joint compiler of the work, was noted in THE LANCET recently.

PHARMACEUTICAL POCKET-BOOK, 1925.

Eleventh edition. London: Pharmaceutical Press, Bloomsbury-square, W.C. Pp. 438. 3s. 6d.

THIS is a direct descendant of the Pharmacy Students' Pocket Note-Book which first appeared in 1906 and was then edited by Mr. John Humphrey. Now, with its new title, and under the guiding care of the Science Committee of the Pharmaceutical Society, it contains much new information of an extraordinarily varied character; in fact, it contains so much that in many directions it supplements usefully the text-books on the subject. In its routine pharmaceutical information it forms a summary for these text-books, which will be useful in revision for the pharmacy student. For the medical student who needs less of the knowledge of the ways of pharmacy, it forms an ample stand-by.

But apart from the portion which touches on straightforward pharmacy there are many tables and sections useful to many folk. The dictionary of synonyms is extremely full, and will help the reader of ancient and modern books on medicines. The section on homœopathic pharmacy is all the more useful in so far as it is now so rarely found. "How to Make an Herbarium" is unexpected, but is interesting. The sections on sale of poisons and the Dangerous Drugs Acts, which end the book, are again of the greatest interest to the doctor and a perusal of them may save him much trouble.

PEDIATRICS.

By Various Authors. Edited by ISAAC A. ABT, M.D., Professor of Diseases of Children, North-western University Medical School, Chicago. London and Philadelphia: W. B. Saunders Company. Vols. IV.–VI. In eight volumes. £18 per set.

THESE three volumes maintain the standard of thoroughness and exhaustive detail found in the previous instalment. Vol. IV. opens with diseases of the pleura and lung, followed by a most valuable section on the physiology of the circulation, congenital heart disease, and the electro-cardiogram in childhood. Acquired heart disease is also fully dealt with. The account of blood diseases by Dr. W. Palmer Lucas is well written and balanced. On the other hand, the sections on infantilism and Mongolian idiocy are left unillustrated, and the latter, a comparatively common condition, is passed over with less than a page in a volume containing 1271. The section on enuresis by Dr. Wilburt C. Davison is admirable. The volume concludes with diseases of the kidneys, bladder, and genital organs.

Vol. V. contains diseases of the face and jaws, with a chapter on orthopædic surgery. The pathology of the bones is ably written by Dr. D. B. Phemister. Tuberculous disease, syphilis, dislocations, congenital and traumatic, of the bones and joints, are well illustrated and complete, and conform in the main to the teaching in this country. The chapter on surgery of infantile paralysis is one of the best. The volume concludes with chapters on tuberculosis and syphilis, malaria, and infection and immunity.

The greater part of Vol. VI. is devoted to the acute infections of childhood and infectious disease in general. Typhoid fever is given in great detail. Under acute rheumatism authors from this country are freely quoted. The treatment of whooping-cough with vaccines and X rays has evidently found more success in America than it has here. Influenza, scarlet fever, measles, and cerebro-spinal fever are dealt with in great detail. The volume concludes with chapters on anæsthesia in childhood, the peculiarities of surgery in childhood, and fœtal malformations. The chapter by Dr. Albert H. Byfield on arthritis deformans, which concludes the volume, is a satisfactory contribution.

THE STORY OF A CITY HOSPITAL, 1848–1925.

Published by the Hospital, Victoria Park. 1925.

NOT long ago the City of London Hospital for Diseases of the Chest changed its name by substituting "Heart and Lungs" for "Chest," but no matter what its official title may be, it will still remain to the medical as well as the lay public "Victoria Park Hospital." Its story has been pleasantly told by Lady Butterworth in a small book which the hospital authorities have just published as an appeal for funds, the whole cost of the publication being borne by certain supporters of the charity. The foundation of the charity was brought about on the familiar and simple lines of 70 years ago, when the need for special institutions was beginning to be obvious to broad-minded people. In 1848 "several gentlemen met at the London Tavern"—long famous, but now gone, and like to be forgotten—in Bishopsgate-street. The object of the meeting was to discuss measures to meet the wants of the poor of the East End suffering from chest disease, especially from consumption. The Brompton Hospital had been founded six years before, in what was then a semi-rural district, and the City-road Hospital was some 14 years older, but neither of these institutions supplied the wants of the East of London. The outcome of the meeting at the London Tavern was a dispensary in Liverpool-street, which was superseded in 1855 by the hospital near Victoria Park. The Society of Friends has ever been noted for its philanthropy, so that it does not surprise us to be told by Lady Butterworth that two-thirds of the members of the original committee of the Victoria Park Hospital were Quakers, as have been some members of its medical staff. Conspicuous among these latter was that kindly autocrat, Dr. Thomas Bevill Peacock, for many years, as Lady Butterworth says, "the guiding spirit of the Institution and almost its ruler," whose memory is perpetuated by the Peacock Ward. Dr. Peacock was also physician to St. Thomas's Hospital, where he died suddenly in 1882, while showing some friends round the building on the Embankment.

These facts and a quantity of others concerning the staff are to be found in an appendix, headed "Personal," which contains brief notes on the physicians and surgeons to the institutions—namely, Henry Jeaffreson, Guy Babington, Aston Key, Erichsen, *Hilton*, *Risdon Bennett*, *Andrew Clark*, James Andrew, Henry Gawen Sutton, and Lord Lister. Of the lay supporters the most outstanding name is that of Mr. Henry Edmund Gurney, who was chairman of the original meeting and treasurer for 18 years, until the failure of the great bank of Overend and Gurney brought him and many others to financial ruin. In Appendix V. a most interesting account of the historical associations of Bethnal Green and Victoria Park is given, for which most of the facts of antiquarian interest have been supplied, as we learn from a footnote, by Mr. A. Forbes Sieveking, the well-known antiquarian, whose father was the famous Sir Edward Sieveking. In 1848 the 200 acres of Victoria Park had recently been dedicated to the public before the neighbourhood had been built over, and when, indeed, it was suburban in character. Adjoining the boundary of the park was a triangular piece of ground of four acres, a part of Bonner's Fields, which the committee of the hospital leased from the Crown, and on which the hospital was built. The Bishops of London had long been connected with Bethnal Green, and Bishop Bonner, of heretic-burning notoriety, had his country house here. Tradition has for long asserted that a house in the neighbourhood of the hospital occupied the site of the palace of the "Blind Beggar of Bethnal Green," whose story is supported by tradition and the well-known ballad, but has no better basis. But Bethnal House, of which the position is indicated on the maps reproduced in this booklet, has an interesting history. Built in the reign of Queen Elizabeth as a country residence, Pepys tells us how he went to dinner there with Sir W. Rider, of his "merry walk with the ladies alone after dinner in the garden; the greatest quantity of strawberries I ever saw, and good." The house was afterwards for many years used as a lunatic asylum, and as Bethnal House it was well known, especially to students of the London Hospital, some of whom still living have studied psychiatry there. It was pulled down in 1921 and its site is now occupied by a public library.

This book is very attractive in appearance and illustrated by maps and photographs, and a facsimile of the scroll commemorating the laying of the first stone of the hospital in 1851. As a frontispiece it has a pleasing colour print of the hospital showing the main entrance and the balconies on the south wing. We cordially share the hope expressed by Sir Alexander K. Butterworth in the preface that its sale may be large and that the charity may benefit substantially thereby.

Ferruginous.

THIS PURE AUSTRALIAN WINE was introduced in 1871, it has been highly recommended by the Medical Profession in all cases where strength and nerve force have required building up. In anæmia, debility, neurasthenia and in convalescence after any illness, this full-bodied, generous wine, palatable as well as health producing, has proved itself the finest of all natural stimulants.

Sample Bottle sent free in the United Kingdom, on receipt of professional card.

MEDICAL SERVICES OF THE MINISTRY OF PENSIONS.

SUCH a war as that from which we emerged some five years ago has ploughed deep furrows into the social and moral conduct of the whole world. The story of the medical services of the Ministry of Pensions, which, as far as it covers that period, is set out by Dr. ALEXANDER SANDISON in THE LANCET this week, is illustrative of the tremendous energies that sprang into being in the days of trial, as of the ghastly situations that had to be faced; and we find the lessons to be drawn from the chronicle of events and from the results of remedial measures to be of good omen along all lines of national endeavour. For in respect of the care and amelioration of our sick and our wounded the objects of the Government, through its differently named ministries, have been attained in a very considerable manner. Aided no doubt by the passage of time and the forces of nature, the widespread alleviation of misery of our injured and disabled has been followed by sound remedial efforts; and in a country where this can take place over one great field of endeavour it is not too optimistic to suppose that similar lifting of post-war clouds will occur over other sections of national endeavour.

Those in charge of the men of our fighting or auxiliary forces throughout the war are now able to look back upon an immensely improved state of things. At the present time the conditions still requiring treatment on any extensive scale at the hands of the medical boards are tuberculosis, insanity and psychical manifestations, and certain general medical and surgical diseases of a chronic type. The victims of tropical diseases have almost disappeared from the lists, while the cardiac subjects have become much more tractable by classification, functional cases being separated from organic, and organic being themselves arranged in manageable categories. Insulin treatment, discovered since the cessation of hostilities, arrived in time to be used to the advantage of the diabetic subjects, while epileptics have been more accurately diagnosed with a view to appropriate treatment. But here, while the task of classification has been carried through successfully, the appropriate institutional accommodation remains to be found. The Ministry of Pensions has no establishment of its own for the colony treatment of epilepsy, and the existing colonies are full, with suitable applicants remaining outside. Here, and elsewhere, things remain to be done, but the whole statement of what has been accomplished shows good results, brought about by steady and unceasing work along intelligent lines; and brilliant as the assistance of specialists in every direction has been, it is particularly gratifying to the medical profession as a whole to know that the principles and problems of the diagnosis and treatment, in reference to the medical charges laid upon the country by the war, have been defined and solved, and the bases of pensions assessments arrived at, in accordance with the average medical opinion of the country. While whole-time officers were appointed to ensure adherence to needful standards and regulations, the claimants for pensions appeared before medical men, usually ex-Service men, whose judgments were arrived at on independent grounds.

During the war the primary object of all treatment was the splendid but horrible one of restoring the disabled man with the greatest rapidity to be an efficient unit in the fighting lines. As the war spread, so the boundaries of the contest came to include territories with a vast variety of diseases associated with their geography, which exacted an immense toll from the forces. Then science entered into hideous coöperation with nature and devised intense methods of warfare previously undreamt of, so that in a short space of time the number of men, whose disabilities obviously precluded them from ever again fighting, mounted up until they became a huge population. Their plight had to be met upon the immediate grounds of compassion and gratitude, and always with the reflection that their futures in civil life were to be secured as far as possible from dependency. At the end of the first year in the war it was clear to everybody that medical treatment must be provided in bulk along many special lines for the benefit of those to whom the nation owed the most poignant gratitude, and thus the Medical Services of the Ministry of Pensions developed out of the responsibility of the fighting Services for their suffering personnel. The Medical Boards, established in the first instance to decide on the physical fitness of recruits, were accordingly so coördinated that they could be adapted to deal with the claims of the seriously or permanently unfit men, and from these were developed the boards of the Ministry of Pensions. Dr. SANDISON's account of the work of these boards is studiously short, but it conveys a vivid general impression of what has been done, and what remains for doing. The figures confirm the tale, showing graphically the steady rise and gradual decline in number of patients, and of institutions designed to meet their circumstances. While many specialised diseases have been appropriately dealt with, a great assortment of miscellaneous disabilities, chronic or recurring, still require special attention. The victims of bronchitis and rheumatism, for example, need greater facilities for institutional treatment at clinics or out-patient departments, and this is especially important because in such conditions the tendency is towards retrogression as time goes on, while it is often particularly important to cut short the development of sequelæ. Much yet remains to be done, but there is no doubt that under the Ministry of Pensions the medical profession as a whole have fought a hard fight strenuously and with fine results.

◆

THE MALARIAL TREATMENT OF GENERAL PARALYSIS.

WE publish in this issue a review of Dr. GERSTMANN's comprehensive account of the treatment of general paralysis by malarial inoculation. The good effects of fever on psychoses has been known certainly for 2000 years, but it was not until 1887 that Dr. WAGNER-JAUREGG, of the University of Vienna, turned his attention to the possibility of curing paralysis by artificially induced fever. He tried and discarded several methods before he decided on the subcutaneous injection of tertian malaria blood; erysipelas, tuberculin, dead streptococci, and proteids were all exhaustively tested. Dr. GERSTMANN gives a synoptic account of 400 cases (those of whom accurate after-histories had been kept) out of a total of 1000, and claims a very high percentage of complete recoveries—about 30 per cent.—with a further 14 per cent. of partial recoveries in which the patients regained a fair measure of social capacity.

The British psychiatrist will want to know how far the malaria treatment has been tried in this country and with what outcome. It must be admitted that the results obtained here have been very disappointing. Dr. GERSTMANN says as much himself in his chapter on the results obtained by other authors, and on turning over the recent reports from a number of our larger mental hospitals (some of which are noted in this issue, p. 405), we find that only a dozen or so have tried the treatment on a few patients, with results so meagre as to be almost inconsiderable. Leicester reports that out of 23 patients 5 fully recovered, 3 were considerably improved, 3 died, and 12 were unaffected. At Chartham Downs one case has been discharged and several benefited, but the medical superintendent feels it is too early to express any definite opinion on the treatment. The one case treated at Barnwood is now free from any abnormal manifestations. Possible reasons for these scanty statistics are (1) this new unspecific treatment may be more likely to succeed in the clinic where it was invented and where everything possible is known about it than it is when adopted by strangers; (2) nowhere in Great Britain could anything like 1000 general paralytics come under treatment in the five years covered by Dr. GERSTMANN'S report; (3) British psychiatrists are still rather suspicious of a method so drastic and empirical and perhaps do not give it frequent trial. A correspondent in our columns this week suggests a milder form of irritant—namely, colloidal sulphur—which might certainly be tried, although the opinion of the original investigators is that the malarial parasite has some specific action. The Viennese experts admit having selected the more promising subjects from their great mass of material during the last two years, and would certainly avoid cases that through age, duration of the paresis, or intolerance of fever would be unlikely to profit by treatment. Certainly it is unfair to condemn a method that has only been tried here and there on batches of three or four patients taken at random. But whatever the reasons for our comparative failure, it would be a great pity if we allowed these results to deter us from testing the malarial treatment on a reasonably large scale. Desperate ills demand desperate remedies; there is very little danger in the treatment to patients of ordinary stamina, and so far no other means has been offered of countering one of the most distressing and hopeless illnesses of our age.

◆

THE IRISH FREE STATE AND THE MEDICAL REGISTER.

THE announcement made on August 15th by the President of the Irish Free State, Mr. COSGRAVE, that the Executive Council of his Government had decided "not to seek the continuance of the United Kingdom arrangement, whereby the medical profession of Ireland, with certain representation, was controlled by the British General Medical Council," has been received with profound apprehension among the ranks as well as in the high places of Irish medicine. Three years ago there was in Ireland a body of medical opinion definitely in favour of the ultimate pronouncement of such a decision, while in our columns in 1922 our Dublin correspondent wrote as follows: "It is suitable that the Irish Government should take under its supervision the keeping of the medical register of Ireland, for it could hardly permit so important a matter to remain in the hands of a body which is departmentally subordinate to the English Privy Council." There is no doubt that our correspondent expressed the attitude of leaders of medicine in Dublin when he wrote, but the probability of a change of opinion was already foreseen. For three and a half years the Government of the Free State has been in communication with the General Medical Council on the matter, leaving the impression of hesitancy throughout, now seeming to regard the functioning of the Council in Ireland as interference, and now viewing it in the light of a useful protection. From the story of the position it will be clear that either view has reason behind it, while the holding of both views simultaneously seems due to that desire "to have it both ways" which is so commonly cherished and so seldom accomplished.

When the autonomous Free State was set up in January, 1922, it was, of course, realised by the medical profession of the State that their whole status might be affected. Those whose eyes were fixed more particularly on the dawn of national existence saw in the opportunity that was thus given to break away from the jurisdiction of the General Medical Council the beginnings of a new and presumably freer era. Others, again, less concerned perhaps with national statesmanship than with the field of medicine within the Empire, foresaw that separation from the British Medical Register, save under the conditions of a Dominion, might imply an economic tragedy for the ancient medical schools of the young Free State. The disaster might be only temporary, but it was difficult to dispute its probability. This latter view has grown to be the predominant, if not universal, one in the medical profession. Further, and apart from purely economic considerations, it is possible that not a few Irish medical men may have felt some damping of their hopes for the future of medicine in the Free State when none of the persons recommended by the Royal Colleges to the President of the Free State Executive as suitable for nomination to the Senate was selected by him for that dignity. At any rate, the change of heart appears to have become manifest soon after this rebuff. It was settled quite early in the history of negotiations between the Provisional Government of Ireland and the British Ministry of Health that the constitutional arrangements then in force as to the Medical Acts would continue unaltered unless and until the Parliament of the Irish Free State saw fit to legislate for practitioners within its own area. And so up to the beginning of 1924 the old way continued unchanged and undisturbed, nor was any voice of complaint uplifted; the understanding being, on the part of the Free State, that should they at any time desire to "cut the painter," they were at full liberty to do so. But following the Irish Free State (Consequential Adaptation of Enactments) Act of 1923, wherein no mention was made of the Medical Act continuing to be in force in the Free State, the General Medical Council indicated that the separation would occur unless the Free State Government explicitly stated that they wished the connexion to be preserved. This brought action from the Free State, and in July, 1924, a Bill was introduced authorising the General Medical Council to continue its jurisdiction for a period of one year. This Bill was passed by the Senate on Feb. 23rd, 1925, from which date it became effective, and the Free State Government was given the opportunity of extending the interim measure for further definite periods.

While professional fears were thus allayed for the moment, the licensing bodies and professional organisations in the State bestirred themselves to find a more stable basis for the future control, educational and disciplinary, of the medical profession in the country. At a conference held in April of this year between the Minister of Local Government and Public Health in the Free State, in whose department the matter lay, and representatives of the medical profession, it was unanimously urged that the existing status should not be disturbed, and that the Government of the Free State should exert itself to ensure that a common register for Great Britain and Ireland should be maintained as hitherto. Our Dublin correspondent says that the Minister agreed with the medical representatives, whom he invited to form a committee with which he might consult as occasion arose. No occasion had arisen before the decision was announced last week to establish a separate Medical Register for the Irish Free State.

Annotations.

"Ne quid nimis."

THE NATURE OF LIGHT.

WHAT life is to the biologist, so is radiation to the physicist, the quickening impulse that sets matter vibrating, not only matter but electricity, electrons, the electrical atoms. These are set vibrating by radiation, and in turn give out radiation and the two processes are linked in some obscure way. The nature of light is, of course, only part of the greater question of the nature of radiation, yet familiarity with the term induces the more frequent reference to it. Newton gave the first connected theory as to the nature of light. His amazing genius coupled experimental inventiveness with a surpassing imagination. The corpuscular theory which he imagined held its own against the undulatory theory for about a century and a half, until the work of another genius, scientist, *doctor*, and Egyptologist, Thomas Young, overthrew it by showing that two beams of light could, under certain circumstances, interfere with one another, and as it were, cancel each other's effects. There was no room for such a *phenomenon* in the theory that light consisted of minute corpuscles ejected from a luminous source. The wave theory of light then held the field for about a century, an enhanced prestige devolving upon it as a result of the work of still one more genius, Clerk Maxwell, whose electro-magnetic theory of radiation retained the conception of undulations, but replaced the mechanical basis of such action by one entirely electro-magnetic in nature. It is probably true to say that Maxwell's electro-magnetic theory of light was held to be true by physicists all over the world at the close of last century, just as the permanence of atoms was by chemists. The discoveries of X rays and radio-activity have modified both of these conceptions. On several occasions Sir J. J. Thomson has pointed out the difficulty of explaining certain phenomena on the wave theory of light, and he has now developed a new theory which attempts to reconcile the two opposing theories, the corpuscular and the undulatory.

It was a happy idea of the Fison Memorial Committee to institute a lectureship to commemorate the life and work of Dr. Alfred Henry Fison, who was associated with the work of the physics department of Guy's Hospital since 1900. The Committee invited our foremost British physicist to give the first of these lectures, and the subject was the Structure of Light. This has recently been published as a small brochure by the Cambridge University Press (2*s.* 6*d.*), the account of the lecture being preceded by an interesting and sympathetic account of the life and work of Fison, a man who endeared himself to mankind generally. Sir J. J. Thomson puts the difficulty of the position in a nutshell when he says: "In all forms of the undulatory theory of light the energy is supposed to be diffused throughout the whole of the space through which the light is passing, and not, as in the Newtonian theory, concentrated in small patches; it is this uniform distribution of energy which has proved the most serious difficulty in the way of the undulatory theory." This difficulty is, perhaps, shown more clearly in what is called gaseous ionisation. It is known that X rays eject electrons from bodies upon which they fall, and it is found that when X rays pass through a gas only a very small fraction of the molecules of the gas so lose electrons; it requires a long exposure to an intense beam of X rays to get one electron out of one molecule in a billion. This is not what we should expect to happen if X rays consist of waves whose energy is spread continuously through space. The same sort of thing happens with gamma rays or ultra-violet rays, but it is rather unusual to get this sort of electron emission by means of ordinary light. In his address on the Structure of Light, which will no doubt become one of the classics of scientific literature, Sir J. J. Thomson develops a theory which is, as he says, a combination of the two older theories. Light is to him partly corpuscular and partly undulatory, a sort of meshwork consisting of active centres on a ground-work of wave-motion. What of these active centres? Herein lies the most imaginative part of the theory, and we read: "The mental picture I draw of the light given out by an atom or molecule is *that it consists* of lines of electric force distributed in two ways. The distribution in one part which we may call the corpuscular and which corresponds to the quantum is, as I shall explain afterwards, an anchor-ring formed of closed lines of electric force; this ring *moves* forward at right angles to its plane with the velocity of light, and this movement does not change its size or shape. The anchor-ring can vibrate, the time of vibration being the time light takes to travel round the circumference of the ring; thus the frequency of its vibration is inversely proportional to its circumference. While it is ejected from the atom it is in vigorous vibration and starts a system of ordinary Maxwellian waves." Further details of this mechanism are elaborated in the text and may be left to the reader. Submitted to experimental test the new theory is likely to fare better than its predecessors, for it reconciles Newton with Young, while paying tribute to the imaginative insight of Faraday, Maxwell, Kelvin, and Rayleigh. Like peaks in a mountain range these names stand out supreme among the British physicists who have brought the study of radiation to its present summit.

ADENOIDS AMONG SCHOOL-CHILDREN.

IN reading Dr. H. P. Newsholme's report on the prevalence of adenoids among Croydon school-children, it is well to bear in mind that this disease, which now bulks so largely in the reports of school medical officers as a cause of widespread damage to health, was only discovered 40 years ago. Thus *in* the eighth edition of Erichsen's "Surgery," published in 1884, we read: "Meyer of Copenhagen has described a condition occasionally met with in strumous children, in which there is a general overgrowth of the closed lymphatic follicles situated about the posterior nares and upper part of the pharynx. It leads to more or less complete obstruction of the posterior nares, and is often accompanied by deafness." The Croydon inquiry was conducted in all the departments of 31 out of the 33 elementary schools, and the survey covered *some 18,000 children*, about 900 of whom had indications of definite adenoids.

Provision of treatment for these children by the Education Committee has altered the normal prevalence of adenoids, and, but for this, Dr. Newsholme estimates that 5 per cent. of the school-children would be suffering from symptoms calling for operative interference, whereas under existing circumstances about 2 per cent. require it. This is a strikingly small percentage; Gradenigo found in Turin that adenoids were present in one out of every three children coming to his clinic, and Dan McKenzie estimates that over 30 per cent. of all children in Britain suffer from adenoids and require operation. The work of the throat clinic now makes adenoids most prominent in early school life, whereas, apart from surgical interference, this disease, high at the entrance age, would increase to a maximum at the age-group 9 to 11. At almost every age-period there is a clear excess among boys as compared with girls. Some 7 per cent. of boys and 6 per cent. of girls have, or have had, definite adenoids during school life. There is some evidence also that the disease reaches a given degree of severity somewhat later in school life among girls than among boys. A comparison between schools receiving children from the more prosperous and the poorer districts respectively suggests a greater prevalence among the latter. Thus 4995 scholars at six schools serving prosperous districts furnished 60 cases of severe adenoids, 47 cases of slight adenoids, and 128 cases which had been operated upon; whereas 4534 scholars in seven schools serving the poorer districts furnished 90 cases of severe adenoids, 69 of slighter adenoids, and 163 cases in which an operation had been performed during school life. There are no data available to check whether the smaller proportion of adenoids among the entrants to the "prosperous" schools is due to more ready recourse to operative treatment during the pre-school age. Among the "prosperous" children aged 5 years, numbering 237, there were seven cases of severe adenoids, three of slighter adenoids, and two where operation was performed during school life; whereas among the 245 "poorer" children aged 5 there were four cases of severe adenoids, thirteen of slighter adenoids, and six cases where operation was performed during school life.

An endeavour was made in the case of 156 unselected cases of well-marked adenoids to ascertain the date of onset. Where a definite history was obtainable from the parents, it was found that half of the cases who were mouth-breathers, one-third of those who were deaf, and one-quarter of those with enlarged tonsils had developed these defects before admission to school. The available data yielded no evidence of any relation between adenoids and bottle-feeding or prolonged breast-feeding, nor did they support the theory that the use of a comforter favoured the development of adenoids. No connexion could be traced between the sanitary condition of the home and the prevalence of adenoids, apart from the fact that the increased aggregation of persons per room appeared to have an influence. It was clear that adenoids cause a school child to lag behind his fellows in educational level, the effect becoming particularly serious in the upper standards of the school.

We hope that this portion of Dr. Newsholme's report will be widely circulated and lead to similar inquiries in other populous districts. One thing is abundantly clear, that we must not be content with moving the maximum incidence from the age of 10 to the age of 5, but that serious efforts will have to be made to tackle the toddler through the child welfare clinics so as to cut off the supply of damaged school entrants. Probably a considerable number of children, both of the poorer and more prosperous classes, have had their adenoids removed before entering school; but it is certain that many children still suffer because the operation has been delayed too long, and that a large proportion of cases of deafness and chronic otorrhœa, as well as of acute aural suppuration and mastoiditis, could be prevented by more timely removal of adenoids. Although some children first develop symptoms of adenoid hypertrophy later in life, the most suitable age for their removal is usually about 4 or 5 years, and in a considerable number of children the naso-pharyngeal tonsil is sufficiently enlarged to cause serious symptoms at a far earlier age than this. A test of the efficiency of the service would be the average age of the patients operated on; it would be interesting to have statistics on this point from some of our public clinics. Croydon should be in an ideal position to do this, as owing to the wise coöperation of the Health and Education Committees the child is supervised, as from September, 1924, by the same medical and health nurse staff from infancy to school-leaving age.

THE THERAPEUTIC USES OF SILICA.

In this country silicic acid and the silicates are generally considered unsuitable for administration per os, although the sodium salt is used in powdered form in France. In a recent article in the *Wiener Klinische Wochenschrift* (No. 27, 1925) Prof. Friedrich Luithlen points out that silica is the foundation of the elasticity of living tissues and that healthy activity depends on the maintenance of a proper balance between the calcium and silica constituents of the body. In youth the silica content is at its highest, decreasing with maturity until in age there is a deficiency, with a corresponding preponderance of chalk. Hence the altered biological processes, the diminished pliability of the tissues, and the liability to fractures. Arguing from these facts, Prof. Luithlen has tried the use of silica in certain senile and other conditions attributable to silica deficiency. The best results have been obtained in cases of pruritus senilis where there is no definite metabolic cause for the irritation and the superficial layers of the epidermis are dry and brittle. In many instances where colloid treatment, hypotonic solutions, and organotherapy had been tried in vain, intravenous injections of silicic acid rendered the skin soft and supple and restored the circulation. Good results have also been obtained in all kinds of senile skin disorders such as psoriasis, furunculosis, and acute weeping eczema in the aged, as well as the further advantage of increased immunity and better conditions of life resulting from the restoration of chemical balance in the tissues. The method has also been applied with satisfactory results to cases of arterio-sclerosis, stenosis of the cardiac valves, and tuberculosis of the lungs. The drug may be administered hypodermically or per os in youthful cases where the power to re-absorb silica has not been lost. For this purpose a "silicic acid tea" or the organic preparations can be used. For older people it is best given intravenously, in the form of a 1 per cent. watery solution of sodium silicatum purissimum. The phials should be well shaken, as sedimentation is likely to take place, and 1 c.cm. may be given on alternate days up to 15 or 20 doses. If the claims of Prof. Luithlen are substantiated by further observations we shall have in silicic acid a most valuable therapeutic weapon against a series of trying and obstinate conditions.

CAVERNOUS OPTIC ATROPHY.

A theory of chronic glaucoma which is associated with the name of Schnabel holds that it is caused not by pressure on the optic nerve, but by primary atrophy of that structure. The theory was long ago discredited, but has lately been revived in a somewhat different form. Mr. Ransom Pickard[1] holds that "cavernous atrophy" is a distinct entity, that it has no necessary relation to glaucoma, but that in some cases the two conditions may be associated. According to this writer, "cavernous atrophy" is characterised by a cupping of the disc which may or may not extend to the margin all round, an absence of tension, which remains within normal limits, and retinal vessels of normal size. The persistence of a normal tension at once separates these cases from those of glaucoma. The fields for colour are characteristic. In ordinary glaucoma they are diminished in the same proportion as the field for white. In cavernous atrophy the colour fields, and especially the field for red, are diminished far more in proportion than the field for white. It follows that in cases suspected to be chronic glaucoma without any demonstrable rise of intra-ocular tension, the colour fields as well as the fields for white should always be carefully taken. From the point of view of prognosis the distinction between the two diseases is, according to the writer of the paper, most important. Several of his cases of "cavernous atrophy" were kept under observation for considerable periods—one case for 14 years—during which time very little progress in the disease took place, and it is his opinion that the case is typical. The subject is controversial and the number of cases from which Mr. Pickard's conclusions are reached is not large, but seeing that cases of cupped discs resembling glaucoma but with normal tension are by no means unknown, it should not be long before further evidence bearing on the subject is forthcoming.

THE PINEAL GLAND AS A LOCALISER.

Radiology may have found a use for the pineal gland. The fact that in about 50 per cent. of all skulls the pineal gland is calcified, and can be demonstrated by skiagraphy, has been utilised by Dr. H. C. Naffziger,[1] of San Francisco, for determining on which side of the brain a tumour is situated. In cerebral tumour the portion of brain affected increases in size and pushes to the opposite side the falx and all mid-line structures, including the pineal gland. This displacement of the gland is termed by Naffziger "the pineal shift." The amount of the displacement varies from 1 to 3 cm. A special X ray technique is described. The "pineal shift" occurs whether the tumour be frontal, parietal, or occipital. Lesions of the base, or of the posterior fossa (subtentorial) cause internal hydrocephalus, and both lateral ventricles being equally distended, no "pineal shift" occurs. The two essentials for this method of diagnosis are a calcified pineal gland and an increase in intracranial pressure. Displacement of the gland to the right of the mid-saggittal plane indicates a left-sided lesion and vice versa. In the presence of intracranial pressure a mid-line position of the gland indicates equal pressure on the two sides. In the chronic form of intracranial pressure, due to tumour or abscess, the medial position of the gland means internal hydrocephalus, which occurs in lesions of the posterior fossa and in distortion of the third and fourth ventricles. In 15 cases the X ray findings have been confirmed either by operation or autopsy.

SAMARITAN FUNDS AND SOCIAL SERVICE DEPARTMENTS.

Reports of the Samaritan funds and social service departments continue each year to provide valuable sociological material of which we do not yet take full advantage. In the report of St. Thomas's Hospital the almoner points out that coöperation between the medical, nursing, and sociological units of the hospital is steadily bearing fruit, and that this coöperation is in turn reacting on the patient. To quote from the report "a new spirit seems to be growing, a desire on the patient's part to be a shareholder, a partner in the fortunes of the hospital; those who contribute a weekly sum from their wages for its upkeep show a more unselfish interest and pride in the good of the whole institution than formerly." The report affords an indication of some of the changes which are taking place year by year in sociological conditions of the hospital patient. For example, a new problem is being raised at the moment in the after-care of the extremely baffling and almost hopeless cases of encephalitis lethargica, and the special departments are receiving patients who, before the war, would not have sought help from hospitals. The rheumatism clinic affords another instance of the value of sociological inquiry and after-care, and it is not too much to believe that this work may be partly responsible for the reduction in the number of cases of chorea which now require treatment in hospital. The over-open door of the casualty department still continues to admit some of the most difficult cases for inquiry, and there is an illuminating passage in the report giving details of the variety of questions which may be presented by one day's casualty work. The almoner comments also on the tasks of daily occurrence which arise in connexion with the patients of no fixed abode who live by casual labour, and states that the number of these patients is tending to increase, a fact which is not surprising in view of the increasing amount of unemployment.

The report of Moorfields Eye Hospital discusses the value of the social service department as a clearing house and a means of putting patients in touch with the various organisations which deal with the blind. Throughout England the Blind Association has visitors who are in communication with their central office, and the social service department of the hospital is thus enabled to coöperate effectively. Patients are frequently ignorant of the provision which has been made for them in various ways by the public authorities, and not the least of the almoner's duties is to help the patient to understand and apply to himself those particular laws and regulations relating to social welfare which have been made for his assistance and not from a desire to interfere with his liberty.

In the report of the Victoria Park Hospital almoner's department emphasis is laid on the housing question. There is little doubt that this outstanding problem remains the chief difficulty in all tuberculosis work. "Patient after patient tells the same tale of ill-health due to being forced to live in over-crowded insanitary houses, and often out-patient treatment in such conditions seems time thrown away." The almoner can only hope to assist certain individuals by repeatedly calling the attention of the appropriate authorities to particularly bad instances. Moreover, the housing problem has a bearing on after-care, which is an important feature of the work in an institution where the question of the return of a tuberculous patient to his own environment is an ever-present difficulty.

The report of Westminster Hospital emphasises similar difficulties. Bad housing again presents one of the greatest hindrances to effective effort; it is almost incredible that in twentieth century England there should be cases of five persons living in one room. The "down and outs," especially among the male patients, also continue to give anxiety. In the case of the older men this may be an unsolvable problem, but in the younger—frequently boys who have wandered to London from the farthest corners of England—some solution should be forthcoming, for it seems impossible to ask the hospital to shoulder the whole burden just because these lads happen to have fallen sick.

The almoner of the Brompton Hospital points out that the coöperation of the social service department of a chest hospital with the medical staff falls largely into two categories—preventive and alleviative; the latter operating indirectly in enabling the patient to obtain and benefit by such means of treatment as are indicated by the physician or surgeon. How wide a field these categories cover may to some extent be imagined when it is realised that patients are taken from all over the British Isles and often from outside them, and that the "coöperation" needed through the social worker may consist of anything from a grant of a daily pint of milk for a few weeks to the removal of a whole family with their Lares et Penates from an East End slum to a Sussex hamlet where house and work have first been found; or again from providing instruction in embroidery to a boy with congenital heart disease, to turning an indolent wife into the family bread-winner. At this hospital the whole ground is covered by the social service department, which deals separately with in-patients, out-patients, and those at the hospital's sanatorium at Frimley. With the latter, every effort is made to keep in touch for an unlimited time, the after-histories thus obtained providing not only opportunities to lend a helping hand, but also a mass of information which has proved extremely useful in various investigations into the results and value of sanatorium treatment. The patients, with few exceptions, respond gladly to requests for yearly reports. All the sanatorium patients are interviewed on their admission by the almoner, who also visits Frimley once a fortnight and makes it her business to smooth away the home and financial difficulties which would otherwise necessitate self discharges before the maximum benefit had been obtained from treatment. A special effort is made to minimise the strain of readjustment to economic and social conditions on discharge. Other inquiries into after-histories are undertaken at the request of members of the visiting medical staff, in which work there would seem to be great latent possibilities. On the preventive side a point is made of arranging prolonged convalescent treatment for debilitated children, especially where there is a family history of tuberculosis or when the children are contacts of definite cases. The hospital possesses, through the generosity of friends, two open-air huts at a convalescent home at Hayling Island, and it is hoped to add to their number in the future. Arrested cases of pulmonary tuberculosis are often boarded out to prevent breakdown.

---

[1] Surgery, Gynecology, and Obstetrics, April, 1925, p. 481.

Even a brief perusal of some of the reports of hospital almoners' departments brings out therefore the outstanding fact that inquiry and after-care are enabling the medical staff to get the treatment recommended carried out.

THE birth-rate of England and Wales for the second quarter of the present year is only 19·4 per 1000, equalling the lowest record of any second quarter of any year excepting during part of the war period. The death-rate for the same quarter is only 11·7, the London death-rate being still lower, and standing at 10·1.

SIR JOHN MACALISTER MEMORIAL FUND.

THE second list of subscribers to the Fund opened by the Council of the Royal Society of Medicine to commemorate the 38 years of service of Sir John MacAlister as Secretary is as follows:—

Dr. W. Seaman Bainbridge, Dr. A. J. Ballantyne, Mr. A. S. Blundell Bankart, Dr. H. W. Barber, Surg.-Comdr. K. Digby Bell, Dr. H. Beckett-Overy, Dr. Arthur F. Blagg, Dr. Thos. William Blake, Dr. P. Brooke Bland, Dr. C. Hubert Bond, Dr. Helen Boyle, Mr. Henry Briggs.

Dr. Aldo Castellani, Surg. Vice-Admiral Joseph Chambers, Dr. Robert H. Cole, Dr. B. N. Colver, Mr. Rupert S. Corbett, Dr. Sidney Coupland.

Mr. F. N. Doubleday, Sir Dyce Duckworth, Bart., Sir James Dundas-Grant.

Dr. T. Watts Eden, Lieut.-Colonel S. C. Evans, I.M.S.

Dr. Leonard Findlay, Mr. Sidney Forsdike, Dr. H. V. Forster.

Dr. R. A. Gibbons, Lieut.-General Sir John Goodwin.

Mr. W. S. Handley, Dr. C. O. Hawthorne, Dr. C. D. Holdsworth, Mr. Montagu F. Hopson, Mr. T. Maudsley Howkins, Dr. J. B. Hurry.

Mr. R. R. James, Mr. George W. Johnstone.

Sir Arthur Keith.

Dr. W. A. Lieven.

Dr. Alastair MacGregor, Sir Hector Mackenzie, Surg.-Captain R. J. MacKeown, Mr. A. G. S. Mahomed, Dr. Archibald Malloch, Dr. A. H. Miller.

Mr. Lionel E. C. Norbury, Dr. Tallent Nuthall.

Mr. T. H. Openshaw.

Dr. Frederick S. Palmer, Mr. Rushton Parker, Mr. James Phillips, Dr. Sidney Phillips.

Sir Alfred Rice-Oxley, Dr. George Riddoch, Sir Hugh M. Rigby, Dr. W. C. Rockliffe, Dr. James W. Russell.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXVI.—TREATMENT OF FLATULENCE.

II.*—INTESTINAL FLATULENCE.

INTESTINAL flatulence gives rise to a sensation of fullness or colicky pain in the abdomen which is due to the presence of gas under tension and is relieved by its expulsion. At times the frequent passage of flatus itself may cause considerable inconvenience. Though the discomfort is felt mainly in the lower abdomen, gas occasionally accumulates at the splenic flexure in such quantity that it may be mistaken for gastric flatulence and an attempt made to relieve it by eructation. If the flatulence be gastric in origin, relief will follow, but if intestinal, there will be increasing discomfort from aerophagy. The differential diagnosis may be readily confirmed by X ray examination.

The intestinal gases arise from two main sources: air swallowed with the food and saliva, and gas evolved from the bacterial decomposition of carbohydrates and proteins. Whilst, under normal conditions, either a small quantity of gas only is formed or a large quantity absorbed so that the amount passing out with the fæces is small, flatulence may occur under the following conditions: 1. Increased formation of gas by (*a*) excessive aerophagy, (*b*) decomposition of carbohydrates and proteins. 2. Deficient absorption of gas. 3. As a result of obstruction. 4. As a result of increased peristalsis.

Increased Production of Gas.

(*a*) Excessive aerophagy may result in intestinal flatulence and the passage of large quantities of odourless flatus.

(*b*) Although a rare occurrence in the stomach, the fermentation of carbohydrates and to a much smaller extent the putrefaction of proteins are common causes of intestinal flatulence. These conditions, though favoured to some extent by constipation, are more usually associated with diarrhœa, and have their origins in a variety of causes of which the following are the most important: (1) Dietetic excesses. The ingestion of large quantities of carbohydrate or protein will tend to produce fermentation and putrefaction from the residue which escapes digestion and absorption. The flatulence which results from the high cellulose dietary often given in habitual constipation is an example of this. (2) *Deficiency in digestive ferments* in the upper alimentary tract. The absence of hydrochloric acid in the various forms of achylia gastrica, and diseases of the pancreas leading to deficiency of its external secretion, will promote conditions favourable to intestinal decomposition. (3) Intestinal infections, whether as a result of infection from the food, from oral or naso-pharyngeal sepsis, or more rarely from chronic appendicitis, may lead to a condition of catarrhal entero-colitis, and by producing intestinal hurry will tend to prevent normal digestion and absorption and lead to fermentation and putrefaction.

Treatment.—The successful treatment of intestinal decomposition depends on the removal of the primary cause and the recognition of the associated disturbance of intestinal function. The stools are often characteristic; in fermentative cases they tend to be acid in reaction, frothy, somewhat sour-smelling, and microscopically show undigested starch granules, whereas in protein putrefaction they are alkaline, have a putrid odour, and microscopically show undigested meat fibre and an excess of Gram-positive organisms.

---

* An article on Gastric Flatulence appeared in this series ast week.

A full consideration of the treatment of these types of diarrhœa is outside the scope of this article, which is concerned with one symptom only—namely, flatulence. This may or may not be of importance, but its efficient control will depend on (*a*) regulation of the diet, and (*b*) use of drugs.

(*a*) *Regulation of the Diet.*—As a means of controlling fermentation and putrefaction much greater reliance can be placed on suitable dietetic modifications than on the exhibition of the so-called intestinal antiseptics which are at best very uncertain in their results.

In *carbohydrate fermentation* the chief source of the flatulence is marsh gas derived from the break-down of cellulose. Green vegetables and uncooked fruits must, therefore, be strictly forbidden, and in some cases the total exclusion of carbohydrates from the dietary may be necessary. Generally, however, sugar, malted foods, milk, purée of potato and celery may be allowed in moderation. Cammidge[1] gives the following diet table for intestinal flatulence:—

The patient may have: White meat, lean red meat, sweetbread, tripe, calves' head, chicken, pheasant, partridge, tongue, lightly boiled or poached eggs, fresh butter, a little sweet cream, toast or old bread, crusts, wholemeal bread, light farinaceous food with fruit juices, spinach, celery, asparagus, a little potato, unsweetened stewed apples or plums, raw apples not too sour, almonds, Brazil nuts, cocoa essence, meat extracts. One ounce of whisky in four ounces of hot water with two meals.

The patient must avoid: Green vegetables (especially cabbage, radishes, peas, beans, lentils, salads), pears, raw plums, mayonnaise, oily or greasy foods, milk, cheese, excess of sweets, pastry, fresh bread, pork, veal, venison, sausages, hare, goose, duck, pigeon, curries, re-cooked meats, smoked fish, eels, salmon, herrings, mackerel, tea, coffee, wine, malt liquors, soup, broth.

In very intractable cases a diet of cooked minced meat and water, the well-known Salisbury cure, may be tried, but it is very irksome and should be limited to a period of six weeks.

In *protein putrefaction* a strict lacto-vegetarian diet is more suitable at first. Chicken, game, and fish may be added later, but mutton, beef, and veal should be withheld for some time after the diarrhœa has ceased. Sour milk is worth a trial in these cases with the object of replacing an abnormal intestinal flora with one inimical to putrefaction. The milk should be sterilised by boiling and then allowed to cool to a temperature of 120° F. A fresh culture of the *Bacillus bulgaricus* (tablets are too uncertain in their action to be reliable) is then added to the milk in a thermos flask and the whole incubated for 18 hours. It is then ready for use and may be taken in quantities starting with half a pint a day and gradually increasing until one and a half pints a day are taken. Better results are claimed by certain American writers, Rettger and Cheplin[2] and Kopeloff[3] by the use of the *Bacillus acidophilus* as the souring agent. They use at least 1000 c.cm. of the freshly inoculated milk and combine it with the administration of lactose, which promotes the growth of the bacilli. The method does not appear to have received an extended trial in this country and there are technical difficulties in the way of its general adoption.

(*b*) *Use of Drugs.*—Drugs are administered with three objects, to aid digestion, to control bacterial decomposition, and to relieve flatulence. In cases associated with achylia hydrochloric acid should be given in the full doses recommended by Hurst, not less than 1 drachm of the dilute acid in a tumbler of water flavoured with orange being sipped during and for a short time after each meal. In pancreatic deficiency various preparations such as pankreon, holadin, and taka-diastase may be tried *after meals*, but are not very satisfactory. Intestinal antiseptics for the control of putrefaction and fermentation are legion, but the evidence of their value is somewhat unconvincing as a satisfactory clinical assay is well-nigh impossible. The best appear to be calomel, especially in divided doses, benzo-naphthol (10 to 15 gr. t.i.d. in tabloid or in cachet), and dimol (2 to 4 gr. t.i.d. after meals). Colloidal kaolin is an efficient absorbent of bacterial toxins and may be given in half-ounce doses in water t.i.d. For the immediate relief of flatulence the essential oils are distinctly valuable, the best perhaps being oil of cajuput (minims 2 on a lump of sugar) and oil of turpentine (minims 15 in capsules or cachets). A tablespoonful of charcoal taken once or twice daily is also useful and helps to render the flatus odourless.

Deficient Absorption of Gas.

As in the case of gastric flatulence, this occurs but rarely, and then as a result of chronic venous congestion in heart failure and hepatic cirrhosis. The main lines of treatment have been sufficiently indicated in the previous article in THE LANCET. Inflammatory conditions of the colon may also interfere with the normal absorption of gases and account, in part at least, for the flatulence complained of in these cases.

As a Result of Obstruction.

Flatulence may occur as a result of organic obstruction or in cases of constipation when the intestine contracts on a fæcal mass and thus imprisons flatus. Treatment is directed to the relief of the obstruction.

As a Result of Increase of Peristalsis.

Apart from the causes already discussed, great inconvenience and distress may be caused by the frequent passage of flatus from causes purely emotional. The condition is analogous to nervous diarrhœa and is liable to be a very distressing symptom in moments of great mental strain. Diet is ineffectual in cases of this type unless, as sometimes happens, there is an associated intestinal catarrh, and treatment should be directed towards lessening the excitability of the gastro-colic reflex by a full dose of bromides combined with belladonna given at a suitable interval before the symptom is liable to occur.

Acute Flatulence or Meteorism.

Acute gaseous distension of the intestines occurs in certain severe abdominal conditions such as intestinal obstruction, acute general peritonitis, and acute pancreatitis. It is met with also as an important complication in certain infective fevers, notably enterica and pneumonia.

Treatment.—Acute abdominal conditions require surgical treatment, but in the absence of intestinal obstruction, or following its relief, the general principles of the treatment of meteorism are applicable to all cases. All food should be withheld with the exception of small quantities of whey and albumin water. Local applications to the abdomen such as turpentine stupes or hot fomentations are valuable, particularly for the relief of pain. Enemata of turpentine (½ to 2 drachms to a pint of soapy water) should be given and oil of turpentine, 15 minims in capsules taken by mouth every three hours, is useful. In severe cases the hypodermic injection of pituitrin 1 c.cm., or eserine 1/50th gr., may be tried in the absence of obstruction. The danger of perforation in typhoid should be remembered and these powerful drugs used with great caution, and only as an extreme measure.

GOVERNMENT LUNCHEON TO STATISTICIANS.—The medical statisticians visiting this country under the auspices of the League of Nations were entertained to luncheon by His Majesty's Government on August 13th. Sir Kingsley Wood presided and extended a very hearty welcome to the visitors. Among the prominent medical men invited to meet the statisticians were Sir Humphry Rolleston, Sir Arthur Newsholme, Dr. H. Robinson, Lieut.-Colonel W. Butler, Dr. Percy Stocks, Dr. J. Brownlee, Dr. Norman White, Dr. J. C. McVail, and Dr. J. Fenton.

Special Articles.

THE MEDICAL SERVICES OF THE MINISTRY OF PENSIONS.

BY ALEX. SANDISON, M.B., B.C. CAMB., B.SC. LOND.,
A PRINCIPAL MEDICAL OFFICER OF THE MINISTRY OF PENSIONS.

THE PRIMARY OBJECT.

THE primary object of army medical treatment was the speedy restoration of the disabled man to be an efficient unit in the fighting or auxiliary services. As the war widened in scope and intensity the number of seriously and permanently disabled men became so large that attention had soon to be directed to the problem of their future in civil life. Thus, early in the war, there was need to consider the provision of medical treatment to those who were *never likely to* return to the forces but for whom the nation began to realise a peculiar responsibility. The restoration of their capacity for civil employment, or failing that the provision of the medical care necessitated by their permanently disabled condition, became a function of the State. Thereafter the medical services of the Ministry of Pensions developed out of the existing but limited responsibilities of the fighting services for the discharged disabled man.

Attributability, Aggravation, and Entitlement.

To medical science the war was as revolutionary an experience as it was to the science of warfare. Fresh problems of diagnosis, treatment, and administration arose on a scale previously unknown. Surgeons had to deal with appalling complexities in septic wounds, physicians were faced with an influx of tropical diseases, and with the novel sequelæ of "gas" and "shell-shock," administrators had to evolve hospital accommodation on a gigantic scale. Latterly there was imposed a new responsibility, novel in principle to normal medical practice, that of determining to what extent the total disabilities of the disabled soldier were due to the stress and shocks of war, and how far, therefore, the State could admit responsibility for them. The word "entitlement" took on a new and technical meaning and with it were joined "attributability" and "aggravation," a trinity of mighty import. "Entitlement" was the foundation-stone on which the structure of the Ministry must rest. Its implications, as defined in the Royal Warrants, depended upon the existence of medical unfitness consequent upon service with the forces. The fundamental decision in entitlement is, therefore, a matter of medical judgment—namely, the confirmation or otherwise of an alleged physical impairment.

ESTABLISHMENT OF MEDICAL BOARDS.

The medical boards established to decide on the physical fitness of individuals for military service were eventually, as part of the Ministry of National Service, so coördinated that they could readily be adapted to deal with the claims of unfit men. From them developed the boards of the Ministry of Pensions with the accessory service of the assessors.

In the Ministry of National Service boards the members of the board were general medical practitioners (assisted as required by specialists) working on a sessional part-time basis, so that the judgments of the boards were unfettered and not open to an accusation of bureaucracy. This principle was maintained in the boards of the Ministry of Pensions. The claimant for pension thus appeared before doctors, usually ex-Service men themselves, whose medical judgment was subservient to no over-riding authority, medical or lay. To function with equity and uniformity, however, the boards required guidance. Whole-time medical officers were, therefore, appointed to coördinate and advise the boards and to ensure an adherence to the technical regulations inseparable from the administration of a large organisation deriving its authority from specific warrants and Acts.

Average Medical Opinion of Country as Basis of Assessment.

Arising directly from a decision that a particular disability was consequent upon war service came the question of the degree of disablement caused thereby. Questions of this kind were new to the majority of the profession. Such assessment, moreover, is by no means easy and affords opportunity for considerable legitimate divergence of opinion. The experience of former wars gave only limited assistance and it was necessary to consider the whole problem largely de novo. Appropriate guidance was therefore given as to the principles on which assessment must be based, with indications of what might be considered an equitable range of assessment for the main types of disabilities and their complications. Except for the assessments fixed by the schedule of the Royal Warrant, these suggestions were based on a standardisation of the assessments which were being made throughout the country by the boards themselves. Thus the main basis of assessment was the average of the general medical opinion of the country. To secure uniformity and equity a special branch of whole-time medical officers, the assessors, was formed to oversee the assessments and discuss with individual boards any instances where their assessments and verdicts on entitlement were out of harmony with that which experience had shown to be appropriate, the final decision, however, resting with the board.

The final development of the boarding and assessing medical services thus resulted in a harmonious combination of the medical experience of the independent general practitioner, the specialist, and the administrator. On the one hand the pensioner was assured of the primary consideration of his case by independent medical men, and on the other of general uniformity and equity of treatment.

Ministry of Pensions Disability Committee.

The Minister, in 1919, appointed the Ministry of Pensions, Disability Committee. This Committee had as its members the Presidents of the Royal Colleges of Physicians and Surgeons, the secretary of the Medical Research Council, and other eminent medical men, who, with the Director-General of Medical Services as chairman and in conjunction with senior officials of the Ministry, medical and lay, considered in detail the medical aspect of the existing principles and regulations. The Committee, with its specialist subcommittees, held frequent meetings throughout 1920, 1921, and 1922. As the outcome of its labours the practice of the Ministry in entitlement and assessment became based upon the highest medical authority. The Committee remains in being and is available when required for consultation on medical problems.

The boards, initiated to deal with applicants for pensions, are now chiefly concerned with renewals and reassessments, although there still occur a considerable number of fresh applications—e.g., for the year ending March 31st, 1924, Article 9 claims averaged 600 a week, and for the year ending March 31st, 1925, there were 23,846 Article 9 boards, of which 730 were for officers. Their work in renewal and reassessment has been further added to by the institution of special boards for final awards. Further, it was inevitable that appeals should be made for reconsideration of the findings of the boards, and in October, 1919, appeal boards were constituted. Their constitution and procedure were on similar lines to the primary boards. It is remarkable that since their commencement the number of claims to these appeal boards has maintained a steady average of but 5 to 7 per cent. of the total cases boarded and that about 60 per cent. of these appeals have resulted in a confirmation of the original finding.

So small a proportion of appeals is a good indication of the efficiency with which the primary boarding and assessing procedure has been conducted.

The magnitude of the boarding work since its commencement is at once apparent in the figures given in Table I.

TABLE I.—*Medical Board Examinations.*

A = Officers. B = Other ranks.

Financial year	Resurveys.		Appeals.		Final awards.

1924–25	3,640	47,227	741	8,922	15,208	212,014

Treatment.

The pensioner having received entitlement and assessment often required medical treatment, but prior to March, 1917, little provision for this had been made. Military hospitals were available if the pensioner liked to apply, but otherwise nothing very definite was done. Article 6 of the Royal Warrant and Order of Council of 1917 completely changed the situation, for, as stated in the Minister's first annual report, "its terms are wide enough to allow of the use of all forms of medical treatment," and "by it the entire direction of medical treatment of discharged men came under the control of the Ministry." From August, 1917, full use was made of these powers.

The facilities immediately available for treatment were military and civil hospitals, but the existing demand on these institutions by men still on the active list and the increasing number of pensioners suffering from special disabilities necessitated the securing of institutions to be controlled by or on behalf of the Ministry itself. The treatment needs of the Ministry increased at a rapid rate, especially on general demobilisation. Table II. shows the development of treatment.

TABLE II.

Date.	Total under treatment.			Special institutions for treatment of war disabilities.
	Institutional.	Otherwise.	Total.	
3/4/1918	10,743	1,824	12,567	—
31/3/1919	35,048	26,605	61,653	46
31/3/1920	24,007	138,629	162,636	72
31/3/1921	26,342	122,476	148,818	113
31/3/1922	28,894	105,600	119,494	95
31/3/1923	18,402	50,788	69,190	73
31/3/1924	16,046	37,719	51,675	70
31/3/1925	10,081	29,991	40,072	70

These figures do not include cases of insanity (about a constant 6000) nor officers and nurses. A detailed analysis of these figures is given below (Table II.A).

PROBLEMS AND PRINCIPLES OF DIAGNOSIS AND TREATMENT.

The problems of diagnosis and treatment were specialised and numerous. The limbless needed limbs, face wounds required plastic surgery, "shell-shocks" demanded a remedy for their multifarious complexes and complications. The insane needed mental institutions and the tuberculous sanatoriums. Men from the East brought with them malaria, dysentery, and bilharziasis. The blind sought training, the paraplegic a home. Trench fever and D.A.H. abounded. The situation was without precedent and analogies were few. Doctors, whether clinicians or administrators, found themselves launched on a little-charted sea.

Guiding principles soon emerged, and before considering in any detail the special forms of treatment provided, it is desirable to outline the course of the provisions of treatment as a whole.

The main divisions of treatment were and are: (1) in-patient, (2) out-patient, and (3) home. Accessory to these came a combination of treatment and training, and the special requirements of limb-fitting.

The use of civil hospitals for in-patient treatment was often handicapped by the difficulty of maintaining effective coördination, and of obtaining regular reports, together with at times a lack of facilities for dealing with the specialised diseases of pensioners. The Ministry therefore, though making extensive use of civil hospitals at the same time, found it necessary to establish institutions of its own. Thus the Ministry has itself been able to develop new methods of treatment, to keep in continuous touch with the progress of the pensioner, and to maintain an adequate provision of the essential forms of treatment required. Out-patient treatment has followed the same general lines and Ministry clinics have come to form the effective basis of such treatment. Home treatment, however, naturally blended with the existing provisions for the treatment of insured persons, and has been in the hands of the local general practitioner, assisted as required by the specialist facilities at the Ministry's disposal.

Such have been the general principles and procedure of treatment provision. The details are best considered according to the types of disability treated. At the present time the conditions still requiring treatment on an extensive scale are tuberculosis, insanity, psychasthenias, and general medical and surgical diseases of a chronic type. Tropical diseases have been almost extinguished. Cardiac diseases have been more precisely diagnosed, the functional being separated from the organic. Diabetics have been given full advantage of insulin treatment, epileptics have been more accurately diagnosed.

Thus the present problems and provision of treatment differ considerably in type and extent from those of 1920. Disease as a whole is characterised by an initial acute phase, followed by a period of subsidence of activity often complicated by expected or unexpected sequelæ, and finally terminating apart from death either in cure or in chronic disability of varying degree. The treatment requirements of the Ministry have necessarily followed this general rule. The acute phase has passed, activity has subsided, and the chief need of to-day is provision for the consequential and chronic terminal manifestations.

1. *Tuberculosis.*

Pensioners of non-commissioned army rank, with few exceptions, were of the "insured persons" class and thus were eligible for "sanatorium benefit." Their treatment for tuberculosis was therefore already provided for through the schemes of local health authorities under the general control of the Ministry of Health. Pensioners, however, have not only been given the full advantage of the existing tuberculosis schemes of local authorities, but in several directions those schemes have been supplemented by the Ministry itself. For example:—

(1) *Treatment for Officers and Nurses.*—Arrangements have been made with sanatoriums at Matlock, Woking, Midhurst, and elsewhere for special accommodation. At Matlock and Nayland sanatoriums provision has been made for vocational training.

(2) *Surgical Tuberculosis.*—The facilities for institutional treatment for adult surgical tuberculosis under local tuberculosis schemes are somewhat limited. The Ministry has, therefore, concentrated many such cases at its own hospital at Orpington where facilities for light treatment have recently been installed and the services of specialist surgeons secured.

(3) *Observation.*—To secure accuracy in the diagnosis of tuberculosis, wards have been set apart in Ministry hospitals throughout the country for the purpose of observation by specialist Ministry medical officers, using the latest methods of diagnosis. Until recently a total of some 200 beds were so occupied, but the need for such observation is now rapidly

Note.—Insanity (about 6000 at each period) and officers and nurses *not* included.

I.P. = In-patient. O.P. = Out-patient. H.T. = Home treatment. Prior to 31/3/22 Aural and Ophthalmic cases were included in "General Medical and Surgical."

decreasing. The work done has been unique in scale and comprehensiveness. A full account of it has been already published in THE LANCET, 1924, i., 1105.

(4) *Treatment Abroad.*—Certain institutions in Switzerland and on the Riviera have been inspected and approved for the treatment of tuberculosis when treatment abroad was deemed essential.

(5) *Special Forms of Treatment.*—(*a*) *Dreyer treatment* was given by arrangement with the Medical Research Council to surgical tuberculosis cases at Orpington and to pulmonary cases at Woking Sanatorium. (*b*) *Light.* The recent advances in treatment by artificial light are being fully utilised and developed.

(6) *Vocational Training.*—In conjunction with the Ministry of Health extensive provision was made for vocational training, and approximately 700 pensioners have completed satisfactorily their courses in various trades and occupations.

(7) *Special diet, overcoats,* and *blankets* have been supplied to cases for which they were specially requisite.

As regards tuberculosis the Ministry has thus fully carried out its responsibility to secure for the pensioner the full use of existing treatment facilities and to supplement them as and when required.

2. *Mental Diseases.*

Under the Lunacy Acts the responsibility for the care of the certified insane rests with local authorities, with the general supervision of the Board of Control. Early in its history the Ministry made arrangements whereby any stigma of pauperism attachable to the admission of a pensioner to a county or borough asylum was removed, and "Service patients," including all those whose mental disease could be associated with the war, were given defined privileges.

The next step was to establish further the liaison with the Board of Control and to secure the regular examination by Ministry specialists of pensioners in mental hospitals. Specialist medical inspectors were appointed to conduct a systematic visitation. The discharged man pensioned for mental disease is thus very carefully looked after and his interests secured. The establishment of mental hospitals for pensioners alone was fully considered, and, although it was not found practicable to make general provision of such hospitals, arrangements have been made with two institutions—the Old Manor, Salisbury, in the south, and Storthes Hall, West Riding, in the north—for the allocation of separate wings (150 and 200 beds respectively) for the exclusive use of "Service patients." The cases selected for admission thereto are those whose mental state allows them to appreciate the advantages of such special accommodation and the scheme has proved very successful. The Storthes Hall wing is under direct Ministry control.

Arrangements have also been made for the accommodation in Ministry hospitals of suitable cases discharged "on trial" from asylums so that the difficulties inherent in sudden change from asylum to ordinary civil life might be minimised.

3. *Neurasthenia.*

The word "neurasthenia" has been widely used to include a large variety of conditions ranging from genuine "shell-shock" ("commotio cerebri") to functional neurosis ("emotio cerebri") and including the minor degrees of neurosis associated with the ordinary ailments and difficulties of life. Cases of true mental deficiency and inherent inability to withstand ordinary stress and strain have also been grouped in this miscellaneous class. The sorting out of this conglomeration of disabilities required time and patience. Moreover, the more acute forms of war neurosis presented novelties of aspects for which at the outset the best form of treatment was a matter of argument and indeed largely empirical. When from the mass provisionally diagnosed as "neurasthenics" those had been weeded out in whom the neurosis was merely superimposed on some definite organic condition such as gunshot wounds, heart disease, or tuberculosis, there yet remained a very large number, broadly divisible as follows:—

(1) *Borderline Cases Verging on Certifiable Insanity.*—It was the aim of the Ministry to avoid certification as long as possible. No adequate provision for the treatment of such cases existed, though it was foreshadowed at Maudsley Hospital, and the Ministry therefore established special institutions of its own, both for officers and other ranks, where every method could be employed to cure the case, or, if cure was impossible, to postpone certification until it could by no means be avoided. Considerable success attended these efforts and the problem of the borderline case is now much less acute. To-day the hospital devoted to such cases is *Ewell* (400 beds), which now serves as the centre to which all such cases in "other ranks" are deflected. For officers, *Latchmere* (58 beds) serves a similar purpose.

(2) *True Neurasthenics.*—Numerous special hospitals and clinics were established to treat these cases, and arrangements were made for the training of doctors in the technique of psychotherapy. Psychotherapy by itself, however, in a considerable number of cases did not produce more than "alleviation," and the reputedly cured neurasthenic was very apt to relapse seriously so soon as he had to face for himself the full stress of life, especially when associated with unemployment or domestic worries. Neurasthenia, moreover, was a too easy refuge for the work-shy and pessimist. Substantial progress in diminishing the numbers of neurasthenics requiring treatment was attained by combining definite *occupational treatment* with psychotherapy. Workshops, with workshop officers, were attached to the neurasthenia hospitals and efforts were made to secure suitable employment for the pensioner on discharge. Prolonged clinic treatment was discouraged and the chronic case was brought into hospital for occupational treatment. These measures not only produced cures, but also enabled the specialists to identify more accurately the different types of neurasthenics and to separate out the mentally defective, the epileptic, and the man who was making the most of his disability. Specialist medical inspectors constantly visited the hospitals and aided in this classification.

The number of true neurasthenics still under treatment is now less, as is also the number of hospitals, beds, and clinics allocated to them There still remains, however, a need for further "vetting' and final decision as to future treatment and pension in many cases.

(3) *Mental Defectives.*—The frequency of this type became very obvious in the progress of the eliminative processes described above. These cases failed to react effectively to any form of treatment and deteriorated on return to the unsheltered conditions of home life. Many caused and got into trouble by their generally irresponsible conduct and habits. Others, whilst proving tractable patients in an institution, had not the stamina to maintain them in home conditions. In short, it became apparent that the only adequate treatment was the provision of shelter from the stress of life, a shelter necessary both in the man's interests and in those of his family and associates.

In 1923 Saltash, no longer needed as a convalescent centre, was adapted as an institution for the reception of cases from groups (2) and (3) above, in whom experience had shown to exist a complete incapacity to maintain even relative normality save under institutional conditions. Occupational treatment was fully developed; and the scheme proved so successful and necessary that in 1924 Harrowby Camp, previously a general neurasthenia hospital, was transformed to the Saltash type. A total of 650 beds is now available for this type of case. This provision by the Ministry is unique and, indeed, epoch-making as a practical effort to deal with a problem which is a national one and not solely one affecting pensioners. The time is now approaching when, apart from institutions of the borderline and Saltash types, there will be no need of special neurasthenia hospitals, adequate accommodation being obtainable by the use of separate wards in general hospitals. The need for neurological clinics is also less, but there will remain for a long time the necessity for a limited number of such clinics.

A large proportion of neurasthenics have been eventually disposed of by transfer to treatment and training centres, such procedure consolidating the improvement produced by occupational treatment in hospital. The in-patient figures for past treatment indicate that there have been over 50,000 separate admissions for courses of in-patient treatment for "neurasthenia."

4. *Epilepsy.*

A primary difficulty has been accurate diagnosis. Many cases so labelled proved to be, in fact, suffering from other organic diseases or to be truly functional. Maghull Hospital (300 beds) has been largely devoted to the precise diagnosis of "epileptics," and following this appropriate treatment has been given. The

Ministry has, however, had no institution of its own for colony treatment of epilepsy, and the demands on existing colonies—e.g., Lingfield and Chalfont—have been so heavy as until recently to entail long waiting lists. The task of diagnosis has, however, now been largely concluded, and Maghull is being used to a greater extent for prolonged treatment as well as observation.

5. *Paraplegics.*

These unfortunate men require institutional treatment of a type as home-like as possible, and for this purpose various small institutions have been used, where every comfort is provided for the pensioner fated, probably, to spend the rest of his days in a paralysed condition. With the opening last year of the Star and Garter Hospital, Richmond, additional accommodation has become available.

6. *Organic Nerve Diseases.*

This term is used to include traumatic injuries of nerves as well as general nerve degenerations. Mention must be made of the surgical skill which has been expended on the suture of nerves followed by re-educative exercises and massage, in many cases with gratifying success.

7. *Facial Wounds.*

Perhaps in no department of war and post-war surgery have such amazing results been obtained as in the treatment of facial injuries. Men with jaws and face smashed to shapeless pulp have been re-created in human form. Infinite patience, the most delicate technique, and sheer genius for this special task were happily at the disposal of the Ministry in the services of its facial surgeons, and the special hospital at Sidcup is world-renowned for the work done under its auspices. Happily the need for such work is now slight, and the Sidcup hospital has changed in function. Since March, 1920, however, 2944 facial operations have been performed there, of which 1156 were specialised jaw and dental work. The value and wonder of this work cannot be expressed in words. It can only be fully appreciated by those who have actually seen the miracle performed, the building up of a human countenance out of a repulsive mass of flesh. For the patients themselves, doomed as they thought to mere existence, shunning the ways of men, their distorted lips and eyes unable to express their human emotions, it has meant rescue from a living death.

8. *Diabetes.*

In 1923 the value of insulin for this disease became well established. The Ministry at once arranged for its provision at Orpington to all suitable cases. In the promptitude and extent to which insulin was used the Ministry was well in the forefront. Between June, 1923, and April, 1925, 215 cases (30 officers, 185 other ranks) diagnosed diabetes were sent to Orpington, and 178 given insulin treatment; 23 were found to be suffering from a less severe though analogous condition, but for which insulin was unsuitable. In a large number of cases definite success has followed the treatment, symptoms have disappeared, and the pre-diabetic body-weight has been regained. Each man, before discharge, has been carefully educated in the technique of continuing insulin treatment at home under the care of his doctor and the doctor fully informed of the treatment already given.

In this, as in other directions, the Ministry medical services have secured promptly for the pensioner the full value of the latest medical research. A further example may be cited in the speedy and universal use by the Ministry of the recently developed technique in the estimation of nephritis.

9. *Tropical Diseases.*

In its early history the Ministry's medical services had to deal with very large numbers of malarias, dysenteries, and other tropical diseases. Malaria was treated by intensive methods and is now rarely met with in active form. Pioneer and successful work was done in the pathology and treatment of dysentery, though there is still need for allocation of about 140 beds in Ministry hospitals for the treatment of intractable chronic dysenterics.

Startling success followed the introduction of the treatment of bilharziasis by antimony tartrate. As far as war pensioners are concerned bilharziasis has been extinguished. Pensioners of former wars have also been treated with equal success. The present need for tropical disease treatment is now very slight—a testimony to the efficiency employed in dealing with them.

10. *Wounds and Injuries.*

Enormous numbers of these required treatment, and special surgical hospitals were required on an extensive scale.

Operative procedure has been supplemented by *massage* and *electrical treatment*, a special Ministry *massage service* being established in January, 1920, and speedily numbering 500 members. Specialised *gymnastic treatment* has been given and the X rays utilised in all their latest developments.

The treatment of *penetrating wounds of the skull and brain*, a branch of surgery peculiarly the province of the Ministry, has been greatly advanced and many cases have, through specialised operations, regained a surprising degree of physical and mental fitness.

Gunshot wounds of the chest, often with foreign bodies retained in the lung, have also been treated with surprising success. At Shepherd's Bush Hospital some 250 cases have been operated on with uniformly satisfactory results, and not a single fatality.

The serious and often novel disabling results of the persistent rain of high explosives during the war have thus been largely counteracted, and wounds of head and chest which in pre-war days would have been considered beyond surgical skill have been repaired and remedied to an unlooked-for extent. Certain wounds, apparently soundly healed, but with bullets or other foreign bodies unremoved, have, however, from time to time suddenly "flared" up into serious activity necessitating further surgical interference, sometimes to an extensive degree. The need for surgical beds has thus not diminished so speedily as had reasonably been expected, and there also still remains a considerable number of chronic surgical conditions of a type very resistant to treatment.

Linked closely with the primary treatment of wounds has been treatment combined with training in trades practicable for disabled men, and a large proportion of the wounded have been passed through the treatment and training centres or referred direct to the training centres of the Ministry of Labour.

The extent of the work of a special surgical hospital is shown in the fact that Shepherd's Bush Hospital from August 1st, 1919, to its closure in March, 1925, dealt with 22,641 other ranks and 771 officers as in-patients.

11. *Limbs and Appliances.*

"Go to the wars would you," says Boult in Shakespeare's *Pericles*, "where a man may serve seven years for the loss of a leg, and have not money enough in the end to buy him a wooden one?" The Great War limbless pensioner has been given not a wooden leg but the latest product of the artificial limb-maker's art and a duplicate as well. Witness these figures as to limbs and appliances (Table III.).

TABLE III.

Year ending March 31st.	Limbs supplied.		Repairs to limbs.
	Legs.	Arms.	
1920	15,621	3,456	12,556
1921	15,391	4,746	19,901
1922	9,469	3,937	26,616
1923	7,589	1,230	33,459
1924	9,257	1,291	31,438
1925	11,102	1,289	31,013

At the end of March, 1925, the Ministry was responsible for artificial limbs in 37,178 pensioners, of whom 1782 were officers. In the year ending March 31st, 1925, 18,470 pairs of *surgical boots* were issued, 1180 being first issues, and 18,817 pairs were repaired. Other *surgical appliances*—e.g., belts, trusses, spinal supports—were supplied in 16,053 cases, 3070 being first issues. *Artificial eyes* were fitted to 3880 pensioners and *spectacles* to 733, in many cases special types of eye or spectacle being necessary. Up to March 31st, 1925, 4878 *hand propelled tricycles* and *invalid chairs* had been issued.

The Ministry, by constant conference and experiment, has given the most careful and specialised attention to discovering a fully effective form of artificial limb and has provided the improved types of light metal limbs. Most leg amputations can now be fitted with an artificial limb weighing not more than 4–5 lb. in place of a previous average of about 7 lb. The mechanical facilities developed in the artificial arms supplied are surprisingly effective. Efficient arrangements have been made for the renewal and repair of artificial limbs, and limb-fitting centres have been so established that such renewal or repair is assured with a minimum of inconvenience to the pensioner.

12. *Cardiac Diseases.*

Here again precise diagnosis was urgently necessary to separate out cases with definite structural lesions from those with functional, non-structural (often neurasthenic) conditions. Eminent cardiac consultants gave their assistance in this process. The treatment of both types has been made more effective, especially by means of graduated physical exercises, and the majority of cardiac cases still under treatment are of the chronic and advanced class for which alleviation rather than remedy is alone possible.

13. *Other Special Conditions.*

Mention must be made of the extensive treatment facilities, in-patient and out-patient, provided for *eye and ear diseases*. Numerous courses of lip-reading for the deaf have been given, and for the blind a close association has been maintained with St. Dunstan's.

Dental defects attributable to war service or closely correlated with pensioned disabilities, such as gastritis and rheumatoid arthritis, have been extensively remedied. Five whole-time specialist dentists have been appointed to coördinate and supervise the work carried out by a large panel of practising dentists. By this supervision great economy and efficiency have been attained.

Convalescent homes have been utilised as required. For *rheumatic* conditions spa treatment has been fully employed in suitable cases.

14. *General Medical Disabilities.*

The more specialised diseases having been appropriately dealt with, there yet remains a medley of miscellaneous disabilities of a chronic or recurrent character, such as bronchitis, asthma, myalgia, and rheumatism, for which definite facilities for more than home treatment are still required at hospitals of a general type, at general clinics, and out-patient departments. These conditions by their nature will continue to require special attention, the more so through their tendency slowly to deteriorate from year to year, or to develop sequelæ demanding more urgent treatment.

15. *Treatment Combined with Training.*

The extensive provision of this has been already mentioned in reference to neurasthenia, tuberculosis, and surgical disabilities. The *object* was to meet the need of pensioners whose disabilities prevented them resuming their pre-war employment, and who required training in a new occupation concurrently with the treatment of their disabilities. Close liaison has been maintained with the Ministry of Labour. At the present time the work is nearly finished, only one Ministry centre (Rednal, Birmingham) remaining open. In the past five years, however, treatment and training has been provided to about 12,000 pensioners, and in addition about 5000 have been transferred direct to the training schemes of the Ministry of Labour. The courses provided have included engineering, carpentry and joinery, french polishing, upholstery, painting and decorating, tailoring, watch and clock repairing, market gardening, commercial subjects, &c. The results in general have been good, but the persistent congestion of the labour market has not made it easy for the disabled man, however well trained, to compete with the physically fit civilian. At one time 3300 beds were available in a total of five Ministry centres.

16. *Laboratory Investigations.*

Modern diagnosis and treatment rest on accurate pathological and bacteriological investigations. Pathological laboratories were established at various centres, but this work has been increasingly concentrated at the Ministry Laboratory in London (recently at Cheltenham-terrace, now at Bulinga-street). This central laboratory is as finely equipped as any in the country, and has performed an amount of work which measured by figures is enormous and in practical value inestimable. The medical staff there has kept in touch with all the latest research. Improvements in technique have been introduced and advances in knowledge made which entitle the Ministry to claim that its pathological services are second to none.

17. *Medical Stores and Supplies to Hospitals.*

Efficiency and economy have followed the conduct of these essential services by a special branch established in 1919.

18. *Nursing.*

With the development of Ministry hospitals a Ministry nursing service became necessary and was instituted in June, 1919, the staff at the end of that year numbering 28 *matrons*, 212 charge sisters, 208 nursing sisters, and 214 assistant nurses. The present staff is 30 matrons, 12 assistant matrons, 216 charge sisters, 206 nursing sisters, and 70 assistant nurses.

19. *Miscellaneous.*

Many accessory items in the general work deserve mention. The introduction and development of *record cards*, whereby a continuous account of the pensioner's medical history is made available for all directly concerned with his treatment or boarding; the grants of *constant attendance allowance* for blinded and other pensioners so seriously disabled as to be unable themselves to perform without aid the common functions of life; the arrangements with the *colonies* and with *consuls* in foreign countries for the provision of boarding and treatment facilities abroad as nearly equivalent as possible to those provided in this country.

20. *Officers and nurses* have been dealt with broadly on the same lines as "other ranks" except that separate institutional accommodation has been provided for them. A considerable number of officers' hospitals or officers' wards have thus been necessary, but at the present time only two Ministry hospitals (Rotherfield Court and Latchmere), both for neurasthenics, are solely devoted to officers, and one (The Spring, Hanwell) to nurses. As few officers come within the provisions of the Insurance Act the arrangements for their home treatment have been a direct concern of the Ministry involving much personal communication with doctors and officers. At the present time over 3000 officers and about 330 nurses are in receipt of treatment from the Ministry. The total other ranks now under treatment is approximately 47,000.

CONCLUSION.

Any condensed account of the work and scope of medical services inevitably resembles a catalogue embellished with statistics. A recital of facts and figures can convey but a general impression of the work done and that yet to be accomplished. The war with its aftermath of sick and wounded was a direct challenge to medical science. The challenge was gladly taken up, and under the ægis of the Ministry of Pensions the clinicians, surgeons, and administrators of the profession have united to exercise and develop to the utmost the resources of their art. The victory has not rested with, but has been wrested from, disease.

I am indebted to Major the Rt. Hon. G. C. Tryon, M.P., Minister of Pensions, for permission to publish this article.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.[*]

(Continued from p. 360.)

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

(App. LXVII. and Q. 18437–18518.)

THIS Society submitted proposals for the inclusion of massage and electrical treatment as an additional benefit to be provided by approved societies, when prescribed by a medical practitioner, for persons insured under the National Health Insurance Scheme. Evidence was given by Sir Cooper Perry and Dr. James Mennell.

The rules of the Society provide that its members are not to undertake any cases of massage except under the direction of a registered medical practitioner; not to advertise except in recognised medical and nursing papers; not to sell goods to patients in a professional capacity, and not to accept secret commissions on the sale of goods. Over 5400 masseuses and masseurs are now registered with the Society, and the majority are qualified to administer, under medical directions, the treatments by massage, remedial exercises, and medical electricity now so generally ordered for a variety of medical and surgical conditions.

The certificates granted by the Society are recognised by Government departments and the medical profession generally. Written evidence of the value of the treatment, and the increasing recognition of it, was submitted from Mr. R. C. Elmslie, orthopædic surgeon to St. Bartholomew's Hospital, and from Sir Robert Jones, who said :—

> There are many conditions of which it must be said that physical treatment offers, if not the only hope of cure, at any rate, the only hope of saving prolonged and tedious convalescence. . . . It is not infrequently possible by the use of physical treatment to reduce the duration of disability by anything from a half to two-thirds, while at the same time rendering the liability to recurrence comparatively small.

The witnesses estimated that 2 per cent. of the insured population would require physical treatment annually—that is, 300,000—and the average cost per patient would be £5 10s. This would mean a total yearly expenditure of £1,650,000, or rather more than 2s. per head of the insured population.

Massage treatment would probably best be administered as part of a hospital service. There is, in any case, probably a higher percentage of insured persons receiving massage treatment in hospitals than at home from their panel doctors, mainly because the accident cases usually go to hospital. There is, however, more medical than fracture work amongst hospital cases, roughly two-thirds medical and one-third surgical.

Sir Cooper Perry agreed with Sir Humphry Rolleston's suggestion that there might be a progressive increase in the use of massage amongst the general population, so that the 2 per cent. estimate might prove to be a considerable underestimate in a few years' time.

IVORY CROSS.

(App. LXVIII. and Q. 18519–18657.)

The evidence on behalf of the Council of the Ivory Cross was submitted by Mr. Charles Davis, Mr. H. D. Grant, Mr. John Hale, and Miss A. E. Fletcher.

This Society began by providing dental treatment for soldiers and sailors, and then went on to pensions, but lately have been providing for the population at large. Their income varies from £5000 to £27,000 a year, and it is their practice to require patients who can afford to pay something towards the cost of treatment to do so, as they appreciate it so much more. About 25 per cent. get free treatment; about 6 per cent. give from 6*d.* to 10*s.*; about 10 per cent. give £1; about 30 per cent. give £2; and about 8½ per cent. give £3.

The witnesses said that they objected very strongly to clinics, and they try to provide that in the service, which is always given at a private surgery, there is no distinction between patients.

> (Q. 18643.) Taking your organisation, is there not a taint of charity about it?—There is in the name only, but not in the way the patient is treated. That is the whole secret of the Ivory Cross. The patient comes to me by appointment made by me to see me. He or she comes to my house. The maid who opens the door does not know that she is not a private patient. She enters my surgery. My nurse-secretary tells me who she is and produces her chart, and that is the first time that it is known that she is from the Ivory Cross. There is nobody outside my surgery knows, and she is treated in every way as a private patient. There is no question of charity thrust at her or thrown at her in any way.

The Society is in favour of dental benefit being made a statutory benefit available for all insured persons, if it can be done without creating a state of affairs disadvantageous to the profession. Payment, it was considered, must be on a case basis and not a capitation basis, and it was recognised that there would have to be a scaling down of bills as in the system of payment of panel doctors in force in Manchester and Salford.

SCOTTISH PANEL CHEMISTS.

(App. LXIX. and Q. 18658–18802.)

The General Council of Panel Chemists, Scotland, whose secretary, Mr. J. Rutherford Hill, gave evidence, is of opinion that medical benefit administration through insurance committees and under the panel system should be continued.

> Prescribing by panel practitioners in Scotland, as a whole is on a very high level, and the relationship between practitioners and pharmacists is one of mutual respect and confidence and helpful coöperation. The matters referred to as needing amendment are comparatively few and are mentioned with a view to their elimination, so that a service already on the whole satisfactory may be brought still nearer to the ultimate ideal. These remarks apply equally to the pharmaceutical service.

There is a difference in the way in which the drug tariff is prepared in Scotland as compared with England and Wales. In Scotland the chemist has a commercial profit on the drug supplied and a professional fee for dispensing it. In England the chemist gets the net wholesale cost of the drug plus a flat rate for establishment charges, plus a dispensing fee. Notwithstanding the lower tariff charge for each item in England the cost per head is greater than in Scotland. As an explanation of this Mr. Hill suggested :—

> (Q. 18729.) As a rule the medicines are more concentrated. The dosage is small, and where a bottle of medicine

---

[*] References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

would require to be repeated probably three or four times in England, one bottle would do for that patient under the Scottish system.

Mr. Hill said that from the beginning there has in practice been ample freedom in the choice of medicines, and it has never been suggested or admitted for a moment that the cost of medical treatment should be allowed to debar any sick insured person from receiving first-class treatment or the use in ample amount of any drug however costly it might be. On this the witness was asked:—

(Q. 18678.) One sometimes hears it said that it is true in theory but not in practice. What do you say to that? That while a doctor may in theory prescribe anything he likes, in actual practice he is constantly being badgered about the expense of drugs, and told to keep it down?—That is, I would say, a misunderstanding in some quarters. It is not true so far as my experience goes. No doctor has ever been challenged on the cost of his drugs as a question by itself. . . . It is discovered sometimes that a practitioner in a district in treating his patients spends three or four times as much money as his neighbour practising in the same district among the same class of people, and that is inquired into.

As regards the arrangements for securing proper economy it was thought that the responsibility for initiating action should be vested in some competent central authority, and the invidious onus of so doing thus removed from the local committee.

Another suggestion put forward was that there should be prohibited the prescribing under a proprietary name of medicines which are well-known definite chemical substances, and the prescribing of secret remedies the composition of which is not adequately disclosed.

Generally speaking, it would be a distinct advantage if the prescribing of proprietary medicines was discouraged and sanctioned only in the case of some new medicament which is a new remedy and for which there is no equivalent non-monopoly substitute.

PRACTICE AMONG THE HIGHLAND CROFTERS.

(App. LXX. and Q. 18803–19171.)

Dr. Alexander Asher, who is a general practitioner in Thurso, Caithness, and in a wide surrounding area, gave an account of his practice, which includes a large number of crofters, small farmers, and fishermen. He said that he sent his operation cases to Inverness and Edinburgh, and that urgent cases were usually admitted at once; his patients generally preferred to go to Edinburgh. Notwithstanding his wide and scattered district, he did not do any dispensing himself excepting in emergencies; the prescriptions were generally taken to Thurso by carrier, &c., and dispensed there.

Dr. Asher thought that compulsory health insurance for crofters and share-fishermen, who are at present outside the Act, would prove a great boon. He suggested that local administration of money insurance benefits in the Highlands and Islands should be in the hands of the clerk to the parish council, and that a county rate not exceeding 2*d.* in the £ should be raised for the purpose of providing hospital, nursing, and specialist services.

NATIONAL FARMERS' UNION OF SCOTLAND.

(App. LXXI. and Q. 19172–19300.)

The evidence in this case was given by Mr. J. C. Henderson, whose principal contention was that the agricultural industry had been paying an undue share of the burden of National Health Insurance, because agricultural work was a healthy occupation, as shown by the large surplus of the Rural Workers' Friendly Society. It was the contention of the Farmers' Union that contributions should be levied on the different industries according to their claims experience, as in ordinary insurance practice, and the greater part of the examination of the witness was devoted, without apparently much success, to trying to get him to recognise that his proposal would involve insuperable administrative difficulties.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Irish Free State and the Medical Register.

THE medical profession of the Irish Free State has been taken aback by the sudden announcement made last week by the Executive Council that the Government had decided to establish an independent Medical Register for the State. Last April the Government asked for the views of the medical profession through its several organisations and corporations, and the medical faculties of the universities. The unanimous opinion of the representatives of these bodies was in favour of maintaining the present system of registration in common with Great Britain. Mr. James Burke, Minister of Local Government and Public Health, whose department dealt with the question, expressed his agreement with the opinion of the medical profession, as put before him, and stated that it was the intention of the Government to pass into law a measure establishing the existent system on a permanent basis. He invited the medical representatives to nominate a small committee with whom he could consult from time to time as occasion might arise. No further consultation took place, and last week this committee was summoned, not to consult with the Minister, but to hear the announcement that the Executive Council had decided to establish a Medical Register for the Free State.

If the decision to establish a separate Register for the Free State is carried out, it can hardly fail to affect the medical schools of Ireland adversely, at any rate for a time. What rights or privileges medical men educated in Ireland may in future be given as regards admission to the General Register must remain uncertain for the present. More than half the graduates and licentiates of the Irish schools practise outside the Free State, and until new arrangements are complete students are unlikely to enter the Irish schools; while they cannot ascertain what may be their future prospects, they will go where they can gain access to the wider Register. In fact, the immediate result will almost certainly be that Irish medical students will seek their education outside the Free State. Unfortunately, the medical schools of the Free State, in Dublin, Cork, and Galway, possess very little endowment, and are almost entirely dependent on the fees of their pupils for ability to carry on. Even a temporary absence of students will mean a severe crisis, and it is hardly too much to say that extinction may follow for some of them. The position is a serious one, and requires very careful handling both on the part of the Free State Government and of those who will have the responsibility of presenting the position from the standpoint of the medical profession. It is to be hoped that the decision of the Executive Council is not irrevocable.

Free State Army Medical Service.

A revision has been made in the scale of salaries of the medical officers of the Irish Free State Army Medical Service. The positions of Major-General and chief sanitary officer, which carried salaries of £1500 and £1250 a year respectively, have been abolished, the highest rank now being that of Colonel, with a salary of £1400 a year. The other ranks in future will be Lieutenant, Captain, and Commandant. The initial salaries in each rank will be 12*s.* a day, £1 0*s.* a day, and £1 17*s.* a day, with periodic increase of salary, rising after five years' service to maxima in each rank of £1 5*s.*, £1 15*s.*, and £2 7*s.*, respectively. As compared with the previous scale the initial salaries are lower, but certain officers after five years' service will receive higher pay than under the old scale.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Medical Qualification in Transylvania: a Harsh Position.

THE peace of Trianon has created a curious situation for our medical students. Nominally, before dissolution of the Empire, Hungary had two universities with medical faculties, one at Budapest, the capital, and the other at Kolozsvár, the capital of Transylvania. While the Budapest University had from 4000 to 4500 medical students, the Kolozsvár University modestly provided for between 400 and 500 students. This was due to the fact that the Budapest medical faculty had the best possible equipment, its members in the years immediately preceding the outbreak of the war having been sent to Vienna, Berlin, Paris, and London to study medical institutions and to copy what was best. The Government did not spare money, and the clinics of the Budapest University inspire the greatest enthusiasm among those who see them. Foreign visitors to the International Medical Congress of 1909 held in Budapest retain a vivid memory of the Budapest clinics; in fact, numerous English and American physicians later came to Budapest for post-graduate medical study. Even Transylvanian students preferred to go to Budapest, not excepting students from Kolozsvár itself. These Transylvanian students, having begun their studies in Budapest, finished in Budapest when Transylvania was torn away from Hungary. When the Roumanian Government took over the Kolozsvár University they employed Roumanian professors and the language of the University was changed to Roumanian, which was a foreign tongue and is still almost foreign to most of the Transylvanian students. As Transylvania is a large territory the number of medical students who were nearing the completion of their studies in Hungary amounted to about 1000. These students, not speaking the Roumanian language, preferred to finish their studies in Budapest, Szeged, Pécs, and Debretzen (the four universities of Hungary) and pass the final examination in the language with which they were familiar. However, when they received their diploma in Budapest or in one of the other three universities, and came home to Transylvania, they received the surprising news that they were not allowed to practise in their own land with Hungarian diplomas unless they passed the final examination in Roumanian. This entailed new work for the students, and it meant at least a year's loss to them. This regulation hurt them the more in that the whole administration of Transylvania remains at present as it was under Hungarian rule.

Salzer Treatment of Stricture of Œsophagus.

Prof. János Bokay, of the Pædiatric Clinic of Budapest University, has made experiments with the Salzer method of treatment for cases of caustic poisoning followed by stricture of the œsophagus. Swallowing potassium hydroxide is a frequent accident in Hungary. Owing to the great economic hardships the wives, even in the middle classes, are now forced to work in offices, millineries, and such like places, leaving the supervision of their children in the hands of the oldest child or of neighbours. Such families live in one room, which, of course, serves as the kitchen, and children have access to bottles containing the alkali. The Salzer method of treatment consists in applying the No. 30 Bass sound, which is a heavy œsophageal sound filled with small shot and soaked in warm water to make it flexible. The treatment is begun from the third to the sixth day following the accident. The sound is left in the œsophagus for half an hour and is reapplied every three or four days for several weeks. While Salzer published accounts of 34 cases thus treated, Prof. Bokay has reported 122. In 110 of these cases no strictures developed. The results were less satisfactory in five of his cases because the treatment could not be applied regularly. There were seven fatalities; in three death was due to perforation of the œsophagus followed by mediastinitis, and in four death was due to the poison itself. Prof. Bokay strongly advises the use of this method of treatment for adults as well as children.

Large Doses of Iron in Pernicious Anæmia.

Dr. Rausch, of the Third University Clinic, Budapest, has put the Lichtenstein, Lindberg, and Barkan method of treating pernicious anæmia to the test. These workers recently recommended for anæmia doses of iron ten times as large as those in general use up to the present. They have obtained good results without any gastric troubles worth mentioning. Following their example Dr. Rausch gave reduced iron in daily doses of ½ g., to be taken in wafers, always before meals, so that any particles of iron possibly adhering to the teeth might be removed by subsequent mastication. In cases of pernicious anæmia in which other remedies had failed he tried on the first and second day 0·5 g. ferri redacti, twice daily, then for two days 0·5 g. four times daily, and then for two days or more 0·5 g. six times daily. No injuries to stomach or intestines have been observed following this therapy. Decided improvement was noted in two out of five cases and a transient improvement in two cases. This method certainly deserves a trial, as it evidently exercises a strongly stimulating effect on the blood-forming constituents of the bone-marrow in cases which are still capable of improvement.

Insurance Doctors' Fees.

The medical advisers of life insurance companies have started a movement here to induce the insurance companies to pay medical fees in proportion to the depreciation of the currency from its normal rate of exchange. The fees at present are much less than formerly. The lowest fee for an insurance certificate in pre-war times was 10 crowns (8*s.* 4*d.*); the fee at present does not amount to 5*s.* As the ratio of the face-value of the policy to the premium is the same that it was in pre-war days, the medical advisers insist on being paid on the same basis. Physicians are ready to refuse medical examinations for insurance companies if the latter are obdurate.

Appeal for Legislation to Regulate Medical Advertising.

Prominent members of the medical faculty have appealed to the authorities to amend the law regulating advertising, and provide that the editors of newspapers, journals, and other publications shall be held responsible for all advertisements or other matters published referring to the practice of medicine or dealing with secret remedies. Advertisements should be held to be of a secret character when they relate to the treatment of any disease or affection without medical confirmation, where the testimonials are not signed by physicians, and where the declarations of treatment are simply guaranteed by laymen or groups of laymen. Penalties, it is urged, should be provided for infractions of these rules.

WIGAN INFIRMARY X RAY DEPARTMENT.—The board of management of the Wigan Infirmary have decided to proceed with the erection of a new X ray department and with the necessary equipment for artificial sunlight treatment. The cost of the building and equipment will be about £9000.

MEMORIAL TO DR. MARY STURGE.—The Medical Women's Federation, of which the late Dr. Mary Darby Sturge was president from 1920 to 1922, has issued an appeal for subscriptions to a memorial fund. Dr. Sturge, who died in March last at the age of 62, was honorary physician to the Birmingham and Midland Hospital for Women and joint author with Sir Victor Horsley of "Alcohol and the Human Body." The money which is to be raised will be presented to the Taylor Memorial Home of Rest for Women at Birmingham for the dedication or endowment of a bed. Dr. Sturge was one of the founders of the home, and just before her death she inaugurated a scheme for the erection of new quarters for the nurses. These are now complete and the building has been named the "Dr. Mary Sturge Wing."

Public Health Services.

MENTAL HOSPITALS SERVICE.

Barnwood House Hospital for the Insane, near *Gloucester*, has accommodation for 150 patients, 15 of them voluntary boarders. The aim of the hospital is to admit recoverable patients and not to use the accommodation for chronic cases. The pathological work is at present dependent on Bristol University, but a pathologist has recently been appointed to the Gloucestershire Royal Infirmary and will undertake the work of this hospital. The medical superintendent calls the attention of his readers to the need for out-patient clinics for incipient cases. Such clinics do not appear to have been established in Gloucester yet. A renovation of the cowsheds of the institution has been undertaken in order to ensure milk-supply under the best conditions. The greater part of the report consists of statistical tables. A curious anomaly appears in the name of the institution, which avoids the obsolete "asylum" and yet retains the almost equally objectionable word "insane."

The Retreat, York.—The 128th annual report shows that the work there is being carried on at the previous high standard. The number of voluntary boarders reaches the high figure of two-thirds of the total inmates. The recovery-rate is 32 per cent. and the death-rate 10 per cent. The malarial treatment of general paralysis is being continued and one patient has been discharged apparently cured. Although there seems no doubt that this treatment profoundly modifies the course of the disorder, each case seems to be a law unto itself. The problem of occupation therapy is being tackled with ingenuity and perseverance, and a great deal has been done to increase output and introduce simple and attractive handicrafts. The universal sense of need for early treatment is being felt by the medical officers, and they are hoping to approach it on somewhat original lines. The report includes an outline of the history of the institution, photographs, particulars from the point of view of patient and nurse, and some useful statistical tables.

The Lady Chichester Hospital, Hove, was a pioneer among institutions for cases of early nervous breakdown. The work is being carried on to the limit of financial possibility and there is always a long waiting-list for the 40 available beds. By far the greater number of cases are able to return to normal life when they leave the hospital; a few go to convalescent homes or become daily out-patients, living outside but spending their day in the easier environment of the institution. All the usual methods of treatment are employed at discretion, particular stress being laid on fresh air and generous diet. Search is made for septic foci, and hydrotherapy and electrical treatment are applied to suitable cases. All kinds of "occupational therapy" are employed, handicrafts, gardening, housework, and work for the annual bazaar being the chief features. Old patients keep in touch by means of the "club night," a weekly entertainment or dance to which all old patients are welcomed. There is no doubt that the work carried on is invaluable for a certain class of patient, and there is scope for considerable extension of the work when funds are available.

Glamorgan County Mental Hospital, Bridgend, supports 1800 mental patients. There is a larger proportion than usual of the congenital class and of recurrences; indeed, the medical superintendent reckons that 70 per cent. of the patients under his care may reasonably be assumed to be beyond hope. The death-rate for the year was 8·4 per cent. The high incidence of tuberculosis and dysentery, partly due to the overcrowding of the premises, has been reduced. A consulting surgeon has been appointed and a local dentist attends when necessary. Every effort is made to interest the junior nursing staff in their work, and 27 have passed the junior examination for the certificate of the Medico-Psychological Institute, but the proportion of failures is very high. The new house, Glan Rhyd, for convalescent male patients on parole is proving very successful, and only eight cases have abused their parole during the year. The report includes notes by the three chaplains and full statistical tables.

The report of the *Staffordshire Mental Hospitals Board* includes the three institutions under the direction of that body. At the *Stafford Mental Hospital* over 1100 cases have been under treatment during the year, the continued steady increase making the question of additional accommodation an acute one. The death-rate has been 6·33 and the recovery-rate 20·33 per cent. among men and 37·69 per cent. among women. The medical superintendent emphasises the importance of early treatment by showing that in 60 per cent. of the recoveries the duration, prior to admission, was less than two weeks, and was over three months in 11·8 per cent. only. The very low tuberculosis death-rate is attributed to the unremitting attention given to ward hygiene and diet, in which the inclusion of "marmite" has played some part. There has been no diarrhœa or dysentery. The installation of electric light and vacuum cleaners has much improved the condition of the wards. From the pathological department two papers have been published: (1) on the production of formaldehyde by intestinal bacteria in connexion with the ætiology of nervous breakdown, and (2) observations on the types of blood-sugar curve found in different forms of insanity. The latter embodied very extensive research and suggested interesting and important differences in metabolism between the sane and insane. In addition, the histological condition of the ductless glands in mental patients has been the matter of investigation.

Burntwood Mental Hospital (Staffs. Co.) has 900 patients, and the general health has been maintained at a high standard. In addition to routine work in the laboratory Dr. G. F. Cobb has been carrying on an investigation into the chemical aspects of epilepsy. The work of the dental surgeon has been of much value.

Cheddleton Mental Hospital (Staffs. Co.) is overcrowded with 1045 patients, including cases of mental defect, and there is a shortage of nurses. Many structural renovations have been put in hand and many more are required. The arrangement of the dietary scale is made difficult by the absence of any gas-supply for cooking. Cheese and marmite are relied on for the supply of vitamins A and B respectively. Orthopædic treatment is to be commenced for suitable cases, and the nurses are to have special training in education methods for the mentally defective. In addition to routine work carried on in the laboratories Dr. F. H. Stewart has investigated the chemistry and bacteriology of intestinal toxæmia. He has found that one variety of non-lactose fermenting organism is regularly present in the fæces of chronic patients when they are undergoing acute exacerbations. The principles of parole and open-air wards are employed with success.

Carmarthen Mental Hospital has 600 patients. The work is hampered by inadequate water-supply and drainage, but a recovery-rate of 36·44 per cent. has been obtained. The cases of excitement greatly exceeded all other forms of insanity on admission. Of the 48 cases discharged as recovered 74 per cent. were in residence for less than a year. The death-rate is 7·70, the proportion attributed to tuberculosis having much diminished. It is hoped to improve the amusement facilities and dietary in the near future.

West Sussex County Mental Hospital, Chichester.—The report records a successful year of work. The 760 patients include private and ex-Service cases. There has been a recovery-rate on the admissions of 25 per cent. with a further 25 per cent. relieved. Special stress is laid on the restoration and maintenance of physical health; every new case is examined as a routine by the specialists in medicine, surgery, diseases of the eye, throat, ear, and teeth; and ten successful operations have been performed. There is complete freedom from infectious disease and only nine cases of tuberculosis are under treatment. Occupational treatment is provided in the farm, grounds, and workshops, and in the domestic departments for women. Parole is given wherever possible. The medical records have been supplemented by nursing report sheets, which have been most carefully kept and have proved a valuable and illuminating addition to the records. A large proportion of the nurses hold the certificate of the Medico-Psychological Association.

Hertfordshire County Mental Hospital, St. Albans, accommodating 1180 patients, shows a recovery-rate of 33·8 per cent. and a death-rate of 6·11 per cent. Extensive use is made of the parole and discharge-on-trial systems and the provision of money grants where needful. Several major operations have been performed and 110 patients have received attention from the dental surgeon. Clinical rooms have been provided in connexion with the admission and infirmary wards, affording opportunity for valuable private interviews. Many of the nurses hold, or are training for their certificates, and the nursing of sick male patients by women has proved satisfactory.

Brighton County Borough Mental Hospital, Haywards Heath, supports 820 cases. Parole has been introduced and four of the female wards have open doors into the garden throughout the year. The dental surgeon has attended 435 patients during the year. Clinical rooms have been provided for three wards, and the provision of verandahs and admission wards for recent and recoverable cases is under consideration. Patients are encouraged to wear their own clothes. A large proportion of the nurses hold the M.P.A. certificate.

Kent County Mental Hospitals Service maintains two hospitals. 1750 patients, including 70 "Service" cases, are accommodated at *Barming Heath, Maidstone*. There is a recovery-rate of 39·6 per cent.; 65·7 per cent. of these taking place within a year of the onset of illness. The death-rate touched the remarkably low figure of 5·6 per cent.; post-mortem examinations were carried out in 84·8 per cent. of fatal cases. Occupational therapeusis is organised under a special officer and the patients are classed in three groups: (1) those able to work by themselves; (2) those able to work in parties; and (3) those requiring individual attention. It is hoped to develop the third class further. Many patients have been sent out on trial, several of them with a money allowance. Most of the nurses hold the M.P.A. certificate.

At *Chartham Downs* (*Kent Co.*) there are 1150 patients, four of whom have been in the hospital since its opening in 1875. Benefit has been obtained in cases of general paralysis by the malarial treatment. As in so many mental hospitals, there is a large number of senile cases which could more happily be nursed in infirmary wards. There have been mild epidemics of influenza and dysentery. The death-rate is 7 per cent. and the recovery-rate 30·7 per cent. Two new blocks for male patients are in course of construction. Many patients have been allowed out on trial, short leave, and parole, although these privileges have not yet been granted extensively on the female side.

The *City of Birmingham* maintains two institutions: *Winson Green* and *Rubery Hill and Hollymoor*, accommodating some 2500 patients. At the former there has been a recovery-rate of 45 per cent. on the direct admissions. The majority of these cases had a stay of from 4 to 12 months in hospital. The death-rate was 8·38 per cent., a drop from the previous year, and the lowest since 1861; post-mortem examinations were made in 79 per cent. The general health has been good except for an epidemic of influenza. Six cases of general paralysis have been treated by malarial injection with resulting improvement, but no complete recovery so far. Some 70 per cent. of the patients are kept occupied about the grounds, workshops, and wards, and there is ample provision of entertainments and sports. Parole and short leave have been extensively granted. At *Rubery Hill* the death-rate has been 6·78 and the recovery-rate 48·6 per cent., with a further 15·8 per cent. "relieved." Special attention has been paid to the discovery and elimination of chronic septic foci, and a staff of consultants and specialists has been gathered as well as a radiographic equipment. The figures given suggest that this method of approach is of the greatest value. The hospital is approved as a training school for mental nurses. The Birmingham hospitals are fortunate in the help they can obtain from the excellently equipped laboratories under the honorary directorship of Sir Frederick Mott.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.§
Bootle ..	12,297	11,126	3778	10,812	31·7
Margate ..	3,255	2,910	1074	847	12·0
Macclesfield .	4,441	—*	1281	784	47·5
Blackburn ..	17,522	15,110	5088† 1284‡	5,450	24·1
Wigan ..	13,575	11,035	3750	7,060	24·0

—* Not given. † Routine. ‡ Fourteen-year-old group.
§ Excluding dental defects and uncleanliness.

Bootle.

THIS report presents a number of features calling for comment. In it is given the actual cost of medical inspection, which is in Bootle 4*s.* 7½*d.* gross and 2*s.* 3¼*d.* net for every child on the school roll. The ratepayers can see that this figure is reasonable considering the district, and compares well with the rest of the country. The work of past years is shown in a table enumerating routine and special examinations from the year 1908 up to the present date; the total of inspections in 1908 was 1565, against 15,048 in 1924. The next paragraph shows some of the results obtained—e.g., malnutrition has fallen from 14·3 to 5·9 per cent. and enlarged tonsils from 11·2 to 7·6 per cent. The number of barefooted children is put down at 2·7 per cent.—they may be better off than others with badly fitting and defective footwear. Bootle is fortunate in having clubs which distribute clogs to suitable and deserving cases.

It was not found necessary to close any school or department for infectious disease during the year. The town is abreast of the times in having zinc ionisation at its aural clinics, a method which seems likely to repay its cost to the community—cutting short cases of otorrhœa which would otherwise proceed to deafness and other grave complications. The treatment is carried out by passing an electric current of 3 milliamps. for ten minutes through the ionising fluid (5 gr. of zinc sulphate to 1000 c.cm. of water) contained in the external ear channel. Dr. F. T. H. Wood considers that in cases of double otorrhœa it is better to restrict ionisation to one ear at a time, while the other ear receives cleansing treatment There are no special schools in Bootle. Arrangements for the treatment of crippling defects include the provision of special hospital beds and the conduct of a remedial exercises clinic. This clinic is staffed by a qualified masseur and his assistant and is supervised by the school medical officer with the coöperation of a consulting orthopædic surgeon. The payment by parents for treatment amounted only to £56 7*s.*, of which £39 19*s.* represented payment for dental treatment.

Margate.

Intimate coördination is maintained between the various health services, as Dr. Rowan McCombe himself carries on the duties of school medical officer, and medical adviser to the medical officer of health, and medical adviser to the infant welfare centre. Commenting on the 75 per cent. reduction in the numbers of unclean children during the past few years, Dr. McCombo draws attention to the increasing practice at some schools, especially among the girls, of wearing a simple tunic uniform—an excellent practice which makes for tidiness and cleanliness and inspires the wish to "live up to the uniform." Goitre is of rare occurrence; only one case, with mild enlargement, was seen in the district. Fifty-eight operations for tonsils and adenoids took place at the school clinic, the children being kept at the clinic for one night following the operation and seen the following morning by the surgeon and again inspected in a week's time. Adequate arrangements are made for the treatment of mentally defective children and deaf-mutes, and severe cases of epilepsy, and a strong plea is put forward for an open-air school to ensure treatment for the anæmic and pre-tuberculous children.

Macclesfield.

The school medical officer, Dr. J. Hedley Marsh, who is also medical officer of health, issues a brief report, much of which is only of local interest. Tonsils and adenoids seem to receive thorough treatment and after operation are carefully followed up, while the parents are advised to see that the children carry out the after-treatment which is clearly described on printed cards. Visual defects rarely fail to secure treatment and dental inspection is well carried out, nearly 90 per cent. of all the children in the schools being inspected by one of the three dentists. Dr. Marsh records, however, that only 31 per cent. of those requiring treatment receive it, and this, as he says, is not satisfactory. There are no special schools in the area, and Dr. Marsh stresses the necessity for a mentally defective school and hopes that one may be established. An orthopædic clinic is carried on at the general hospital and good work is evidently done at the general school clinic.

Blackburn.

Dr. W. Allen Daley reports progress in organisation during the past five years. An additional age-group has been included—viz., the "leaver" or 14-year-old group. Almost all the clinics began within this period and lately there has been added an orthopædic clinic for early treatment. He regrets the delay that occurs in dealing with adenoids, owing to lack of accommodation. Dr. Ella Mackenzie found that of the children who should have been wearing glasses only 75 per cent. were doing so. Taking into consideration the large proportion of spectacles worn which are no longer efficient, the need for some kind of spectacle "roll call" is evident. Since the hearing of every child of 8 years has been tested by the "forced whisper" the percentage of minor defects of hearing has risen from 0·4 to 1·5 per cent. Dr. Daley hopes for an increase in the clinics and for further accommodation in the open-air school and classes, and regrets there is still no physically defective school. On the other hand, there is a good mentally defective school, and a return by the late headmistress, Miss Clayton, deals with 140 scholars since 1010 who can be traced. Of these 100, or 75 per cent., are in work. This figure shows how much such a school can do when run with zeal and ability.

Wigan.

Dr. H. Whitehead's report is a concise statement of facts with little comment, but obviously the school medical work is handicapped by inadequacy of staff. The numbers examined in the code groups are incomplete—the same lacunae have stood in the way of a thorough control of measles. Since only one half-day a week has been available for refraction, about one-third only of the cases receive prompt attention. Dental work, too, was similarly limited, but recently the dental sessions have been increased. There is a lack of special schools of all types; a few mentally defective children are attending classes for the dull and backward, but the accommodation is inadequate and such classes have not the power of salvage that belongs to good special schools. A school camp was held with beneficial results, but this is a poor substitute for a permanent open-air school. There appears to be none of the special methods of dealing with cripples by which so many children are cured or made self-supporting in other areas. Good coöperation is maintained between the various branches of the medical services, and records from the welfare centres are available in the schools.'

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 8TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 63; scarlet fever, 1250; diphtheria, 691; enteric fever, 85; pneumonia, 415; puerperal fever, 37; cerebro-spinal fever, 8 acute poliomyelitis, 7; encephalitis lethargica, 41; continued fever, 1; dysentery, 8; ophthalmia neonatorum, 110. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 22 from measles, 8 from scarlet fever, 28 from whooping-cough, 18 from influenza, and 20 from diphtheria. There were 108 deaths of children under 2 years from diarrhœa and enteritis, as compared with 101, 64, 50, 44, and 20 in the preceding weeks. In London itself there were 8 deaths from diphtheria, 3 from whooping-cough, and 6 from influenza.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

J. S. Elliot is re-entered as Surg. Lt. Comdr. with seniority of Sept. 20th, 1023.

Surg. Lt. Comdr. P. W. Carruthers is placed on the Retd. List.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lts. to be Surg. Lts.: D. R. F. Bertram and R. Wear.

ROYAL ARMY MEDICAL CORPS.

Maj. J. C. G. Carmichael retires on ret. pay and is granted the rank of Lt.-Col.

The undermentioned Capts. to be Majs.: E. W. Wade, W. K. Morrison, E. Percival (Prov.), and H. C. D. Rankin (Prov.).

ARMY RESERVE OF OFFICERS.

Capt. A. Robertson, late R.A.M.C. Spec. Res., to be Lt.

Capt. G. C. F. Roe, late temp. Capt., R.A.M.C., to be Lt.

TERRITORIAL ARMY.

Capt. A. E. L. Devonald, having attained the age limit, is retired and retains his rank.

Capt. C. A. R. McCay (late R.A.M.C.) to be Lt. and relinquishes the rank of Capt.

Lt. C. M. Bradley (late R.A.M.C.) to be Lt.

E. W. Ashworth to be Lt.

ROYAL AIR FORCE.

Flying Officer F. K. Wilson is promoted to the rank of Flight Lt.

INDIA AND THE INDIAN MEDICAL SERVICE.

The following are granted leave: Lt. F. W. Mathews, Civil Surgeon, Ghazipur; Maj. H. P. Cook, Civil Surgeon, Allahabad; Lt.-Col. F. W. Sumner, Civil Surgeon, Simla (East); Maj. T. C. Boyd, Chemical Examiner, Bengal, and Professor of Chemistry, Medical College, Calcutta; Capt. R. H. Malone, Acting Director, Bombay Bacteriological Laboratory; Major R. Knowles, Professor of Protozoology, School of Tropical Medicine and Hygiene, Calcutta; Lt.-Col. Macmillan, Civil Surgeon, Simla; Lt.-Col. A. W. Overbeck-Wright, Superintendent, Lunatic Asylum, Agra; Lt.-Colonel G. Hutchinson, officiating Inspector-General of Civil Hospitals, United Provinces; Col. A. W. R. Cochrane; Lt.-Col. I. M. Macrae, Lucknow; Lt.-Col. R. F. Baird; Maj. P. B. Mills, Civil Surgeon, Bahraich; Lt.-Col. W. S. Willmore, Civil Surgeon, Cawnpore; and Lt.-Col. T. W. Harley.

NEW MEDICAL COLLEGES IN INDIA.

The King Edward Hospital and the Gordhandas Sunderdas Medical College, fully equipped institutions established by the Bombay Municipality, were opened in July. The Medical College is the first unofficial medical institution in Bombay city and had been recognised by the University of Bombay. Last month also saw the opening of the Prince of Wales's Medical College at Patna and the laying of the foundation-stone of the Wadia Maternity Hospital in Bombay.

FAMILIAL ABDOMINAL LESIONS.

To the Editor of The Lancet.

Sir,—The interesting article by Mr. G. P. B. Huddy in your issue of August 8th raises once more the question of the relative importance of heredity and environment in these conditions, and whilst it might seem that Mr. Huddy favours the heredity hypothesis, a closer examination of his paper makes it clear that this is not the case. A family history of "indigestion" is by itself too nebulous to allow of any accurate deduction being made; extensive family histories of duodenal ulcer or gall-stones, such as are quoted, are very striking, though it is a little surprising if only two examples of such convincing histories occurred amidst 300 patients.

The following example recently came to my notice. The father had a gangrenous appendicitis in 1900 and a perforated duodenal ulcer in 1922. Of his three sons, the eldest had acute appendicitis in 1917, the second a gangrenous appendicitis in 1919, and the third a gangrenous appendicitis in 1914. It is dangerous to assume an hereditary factor from such data; the patients referred to have long been known to me as voracious eaters, but whether this is hereditary or environmental I would hesitate to say. Further, I know that for many years they were attended by an unqualified dentist whose technique was neither orthodox nor desirable.

One can imagine the difficulties of an Eastern physician when asked to write upon a "family history" of salpingitis in the harem of his ruler. On the whole the infective theory remains tenable.

I am, Sir, yours faithfully,

London, W., August 12th, 1925. T. Izod Bennett.

To the Editor of The Lancet.

Sir,—Two years ago, when Mr. James Sherren delivered a lecture in Dublin on Gastric Ulcers, he drew attention to the fact that these ulcers might run in families. I was very interested, as at that time my father had under his care a case of gastritis whose father had died six months previously from gastric carcinoma. I investigated their family history, and now that attention has been drawn to this point in your journal, I think the facts of interest.

The grandfather of the present patient suffered from constipation and dyspepsia. He had to walk about during his meals "to bring up wind." He died from what was diagnosed as "perforation of the intestine." In appearance he was tall, thin, and pale. He neither smoked nor drank. Of his children one showed no signs of gastric symptoms and was unmarried. The second had occasional indigestion, and died from pneumonia. The third had a typical duodenal ulcer, the clinical signs being confirmed by X ray examination. He refused an operation. His only child was healthy. The fourth, the father of the patient, died from cancer of the pylorus, and the patient, aged 21, suffers from agonising pains about one hour after food, with acid eructations. He has never vomited, and refuses to be X rayed. His sister and brother are quite healthy. The remaining two children were daughters, one of whom living abroad suffers from "indigestion, particularly after potatoes," and her eldest child, aged 15, has frequent gastric attacks. The last child when 21 suffered from a typical acute gastric ulcer, and has done so at intervals throughout life. Her eldest child when 21 developed symptoms of duodenal ulcer, with attacks that recur each Christmas. He also refuses X ray examination. Her second child at about the same age commenced to suffer from indigestion, but on rigorous dieting these attacks pass off. They have all lived normal healthy, hygienic lives, are of good physique, and the present generation possess perfect teeth, and, with one exception, are practically non-smokers and non-drinkers.

I am, Sir, yours faithfully,

Sylvia B. Wigoder, M.A., M.B., T.C.D.

Dublin, August 17th, 1925.

SUBCUTANEOUS INJECTION OF COLLOIDAL SULPHUR IN NEURITIS.

To the Editor of The Lancet.

Sir,—I will be much obliged to you if you will do me the honour of publishing the following questions as regards Wagner-Jauregg treatment of dementia paralytica. So far as my personal knowledge goes, I believe that the therapy is still empiric; I have not yet come across any scientific explanation. I assume there is nothing specific in the organism of tertian malaria, the remissions obtained, whether complete or incomplete, being in all probability due simply to the changes of the body temperature. I have obtained encouraging results in certain forms of chronic neuritis with the intramuscular injections of colloidal sulphur (sulfoidol Robin). Symptoms imitating malarial rigor followed. No new infection is introduced to call for quinine—for example, to mitigate the effects of an inoculation. The proceeding, I think, may be used as an argument to prove or disprove the specificity of the tertian plasmodium in the method of treatment, though I believe no such property is claimed.

I am sorry I have not yet met any case of dementia paralytica through eight years practice of the profession. This may be due to the fact that malaria is endemic in this country and syphilis comparatively rare. I shall be very grateful to any member of the medical profession who will test the use in appropriate cases of colloidal sulphur in this way, and will communicate the results through the pages of The Lancet.

I am, Sir, yours faithfully,

Palestine, July 23rd. Djamil F. Tutunji, M.D.

THE ÆTIOLOGY OF CANCER.

To the Editor of The Lancet.

Sir,—The reminder by Sir Charles Ballance of the views held by the late Mr. Shattock, than whom there was no one more conversant with the clinical as well as the pathological knowledge of cancer, brings into prominence the conviction of the clinician, that tubercle, a known parasitic disease, sarcoma and carcinoma in their modes of onset, in their course, in their termination, and in their curability are more or less alike. It took 40 years to discover the tubercle bacillus after tuberculosis was pronounced to be of this class, and for over 30 years the hunt for the parasite of sarcoma and carcinoma has been going on and has not yet been actually successfully finished. Indeed, there are signs that the hunt may once again be side-tracked. While the clinician has no difficulty in recognising cancer as a member of the great group of parasitic diseases, the pathologist has ever found a stumbling-block since the great advances in histological discoveries during the nineteenth century. Tubercle originates in connective tissue, so does sarcoma, but cancer begins in an epithelial covering. The parasite in tubercle makes a tubercle nodule and when that is completed it starts another, and each nodule is made for and by the parasite. The proliferation of cells is started by the parasite and food in abundance is produced by them. In carcinoma, a parasite—let it be assumed—locates itself in an epithelial cell, makes it reproduce itself and elaborate food—a special food for the parasite. The parasite by its vigour stimulates growth and the new cells thus formed make for it all it needs for propagating itself and for increasing its vigour and strength. In all subsequent growths in other parts of the body epithelial cells like those of the original growth appear. The unsolved problem is how that happens. Does the parasite carry with it an epithelial cell or a derivative which is equivalent in reproductive powers to a full-grown cell, or has the parasite power, wherever it locates itself, to induce a connective-tissue cell to become transformed into an epithelial cell, the only kind it is associated with and the only one that is capable of elaborating its special food?

The former view has held its ground for many years and the lymph and blood circulation mechanism has been considered a sufficient cause for the spread of the new growth into distant parts of the body. Often that explanation is very inadequate, and surely very untrustworthy. A parasite, like every other living thing, seeks its food, and one of the bacterial groups obtains it by creating activity in cells around and by making them elaborate what it wants. It then often kills its host by exhausting the supply of nutriment or by locating itself, perhaps accidentally, in a vital part. To attain its purpose effectively the parasite of cancer should possess the power of converting a cell of the connective tissue into an epithelial one, the only form capable of elaborating suitable food for the special parasite of cancer. Biologists may know of instances in which cells, under appropriate stimuli, become converted into other and distinct forms with different functional properties. In pathology there is not, to my knowledge, an evident example.

I am, Sir, yours faithfully,

Cambridge, August 15th, 1925. JOSEPH GRIFFITHS

To the Editor of THE LANCET.

SIR,—The letter of Sir Charles Ballance in to-day's issue of THE LANCET calls for a reply on my part.

The late Prof. Shattock was almost alone among well-known pathologists in adhering to the parasitic theory of cancer. Apart from him, pathologists in this and in other countries have been almost unanimous in rejecting the theory on the grounds that it is incompatible with the phenomena of cancer. The supporters of the theory have been almost entirely bacteriologists and clinicians, and they have never taken the trouble to meet the objections which have been brought against it by pathologists.

Prof. Shattock did not have before him the evidence that it is possible to induce cancer at will without taking the supposed parasite into consideration nor, until his later years, was he aware that it is possible to cultivate tissue cells in vitro.

The cancer germ cannot be present in the irritant used to produce cancer since this has frequently been submitted to temperatures of 800° C. or over and is thus not comparable with the tuberculous dust to which Sir Charles Ballance refers. If the parasitic theory is true the germ must therefore, as I have said, be present either in all animals or in the atmosphere. The former alternative is negatived by Dr. Gye's facts, since, if it were true, it should be possible to produce cancer by his "specific factor" alone, which is not the case. We are thus left with the conclusion that this intracellular germ is universally diffused in the atmosphere! Can any of those who support the theory suggest any other alternative?

I am, Sir, yours faithfully,

Manchester, August 15th. CHARLES POWELL WHITE.

To the Editor of THE LANCET.

SIR,—The work of Dr. A. S. Leyton and Dr. Helen G. Leyton on the streptothrix in sarcomata, to which Dr. W. M. Crofton aptly refers to your issue of August 8th, was amplified later (1917) thus: Prof. Leyton kindly showed me his microscopic preparations of the organism, and I found the appearances tallied with those I had been finding within the nuclei and cytoplasm of the blood cells in cancer subjects at the Leeds General Infirmary. When I then showed him my preparations it was arranged that he would make blood cultures by his customary technique on the next case in which I should find these structures in abundance. This was successfully carried out, and the cultures obtained agreed in type with those he had already secured from tumour filtrates.

The views in Dr. James Young's letter, so ably stated, can be quite endorsed by my own experiences since the above (and since the reference in "Medical Annual," 1921, pp. 63, 64). The fact, too, that Rickettsia bodies are so widely distributed within the bodies of invertebrate animals seems to show that they may form an essential feature of bacterial life-cycles.

The difficulty which has arisen about the "law of fixity of form" is not insoluble. It comes from supposing that all life-forms must obey it. On the other hand, it does not follow that the lowest forms which are to be found within the body of a higher organism are "normal components of the body," to use the words of THE LANCET (July 25th, p. 183). The body or cell may be providing the necessary substrate (during a varying period of time) for a separate life-cycle. This possibility, and the fact that there are ultra-microscopic phases of life, was stated as long ago as 1878 by L. S. Beale in "Microscope in Medicine" (p. 317, &c.), and he pointed out that they can withstand a temperature of 148° C. The place to which he was disposed to assign these minute bodies in the scale of life is that which they seem likely to receive now.

If the prevailing, and materially favoured, school of thought of to-day is now prepared to entertain Béchamp (THE LANCET, ibid.), surely other concessions will follow. For instance, after all, Bastian's work on heterogenesis was not all an incorrect observation. The diverse aspects of life seen by different observers are capable of harmonisation.

I am, Sir, yours faithfully,

Hartley, Longfield, Kent, August 10th. O. C. GRUNER.

DISABLEMENT FROM CHRONIC RHEUMATISM.

To the Editor of THE LANCET.

SIR,—As one of the signatories of the letter which appeared in THE LANCET under the above heading in your issue of July 11th, I have read with much pleasure Dr. Mennell's communication of August 1st.

I am entirely in accordance with Dr. Mennell's views. In the second paragraph of his letter he lays stress on the importance of increasing the fluid intake of patients who are suffering from the non-articular forms of rheumatism. This I can fully bear out as a result of my experience when practising at Harrogate. In such cases one or other of the mineral waters are prescribed practically as a routine, and I have been repeatedly struck with the improvement which quickly takes place following the increased ingestion of liquid. The reason for this is not far to seek if we can regard these non-articular forms of the condition as being due to changes in the plasma whereby the products of muscular activity are inefficiently removed or, in other words, due to an inhibition of the metabolic exchange which results from muscular action. The absorption of comparatively large quantities of fluid which is isotonic with the blood must of necessity greatly assist the removal of waste products.

I think there can be no question that endocrine disturbance plays a greater part in the production of arthritic changes than is generally realised. Attention has been repeatedly directed by many observers to the probable inter-relationship between alterations of the thyroid and arthritic affections. After all the "make up" of an individual is largely dependent on the harmonious action of his endocrine system. The variation in the train of symptoms in different people which arise from the same stimulus is quite explicable on these lines. Broadly speaking, we can classify groups of cases according to their reaction and for these groups we can revive the old name of "diathesis." We should thus define "diathesis" as a disease tendency depending on an altered blood admixture. From this point of view we are quite justified in speaking of an arthritic diathesis. Such a diathesis shows certain more or less well-defined types. We have the young nervous female with tachycardia, sweating, pigmentation, and various trophic changes with general metabolic upset who tends to develop symmetrical joint changes beginning in the smaller joints. Then we have the stout, well-nourished woman who about the time of the menopause begins to have coarse synovial changes in the hips or knees. These changes are accompanied by all the signs of mild thyroid deficiency. We have also the pale, anæmic, sweating child with a dicrotic pulse, tachycardia, arrhythmia, and a tendency to dilatation of the right ventricle. Such a child is particularly liable to attacks of pyrexia with pain and stiffness of the joints and the formation of fibrous nodules.

Space does not permit a detailed consideration of the rôle played by infective foci in the production of what we term "rheumatic disease." So far as my own experience goes I should certainly say a great deal depends on whether the "exudate" or pus from the focus is under pressure. Pus exuding from a tooth socket is not nearly so likely to cause trouble as a locked-up apical infection. The most dramatic recovery I ever saw followed the removal of an old inflamed appendix from a man who for years had never been free from attacks of arthritis affecting practically all his joints in turn. After his operation he never had the slightest sign of any joint trouble.

As stated in the concluding paragraph, it certainly is a fact that all cases of so-called rheumatism are not what they seem. In this connexion I would say that one should never diagnose a non-articular case as "rheumatic" until every other possibility has been excluded. A very large number of such cases are really due to definite injury with possibly a certain amount of subluxation. This is a veritable pitfall for the unwary, and if after a course of soothing lotions, liniments, and medicine the case falls into the hands of a bonesetter, who, recognising the condition, corrects the deformity by forcible extension and manipulation, and effects a speedy cure, the regular practitioner is apt to feel that "his eye has been badly wiped." The retention of the term "rheumatic" as a description of an ill-defined group of diseases which only agree among themselves in having no connexion with that acute and subacute infection we call rheumatic fever, requires a certain amount of justification. We can only justify it by saying that when we speak of rheumatic disease we know what we mean and that we are referring to a group of conditions whose ætiology has not been thoroughly worked out. With the advance of our knowledge the term will come to be used less and less frequently and finally only applied where it should really belong—viz., to the acute and subacute infections.

I am, Sir, yours faithfully,

MATTHEW B. RAY.

Bentinck-street, W., August 17th, 1925.

INDISCRIMINATE SALE OF POISONS.

To the Editor of THE LANCET.

SIR,—There is no record of achievement of which we as a nation have more reason to be proud than our organisation of public health, but there is at least one black patch which ought to give rise to very different feelings.

Scarcely a day passes without its tale of suicide, and in too many cases the cause of death has been found to be the taking of poison. It is not the primary poisons that are guilty (their restriction has served its purpose well) but the ordinary "household" poisons, of which spirits of salt is the chief. This can be sold by any shopkeeper as long as it is contained in a poison bottle and labelled "poisonous," and bears the name and address of the seller. These restrictions are not enforced and are consequently disregarded every day.

This indiscriminate sale of poisons, for which there must be substitutes for household use, constitutes a grave public danger, and calls for the action of the authorities in enforcing the law as it stands or restriction of the sale with the utmost stringency.

I am, Sir, yours faithfully,

J. H. WILLIAMS.

House of Commons, August 12th.

THE SUPPLY OF VACCINES TO PANEL PATIENTS.

To the Editor of THE LANCET.

SIR,—As a warning to other panel doctors, I submit my experience of trying to obtain repayment from the Middlesex Insurance Committee of the cost of a vaccine used for a panel patient.

In January last I sent the receipted pathologist's bill to the Committee with a request for repayment. Repeated applications failing to obtain the courtesy of a reply, I recently instructed my solicitors to take proceedings. Their first letter was ignored, but the threat of a writ seems to have stirred the official mind from its hebetude, and I have now, after seven months, received a cheque, without comment or explanation given. I understand from my solicitors that, in point of fact, there would be some legal doubt on whom a writ could be served in such a case.

I am not encouraged to repeat the experiment of using vaccines for panel patients, so long as the present system is in force of making the panel doctor pay the cost himself, in the first place, and getting a refund later, if he can, from the Insurance Committee.

Why cannot the pathologist's account be met by the Committee direct?

I am, Sir, yours faithfully,

C. WILLETT CUNNINGTON.

Dollis-avenue, Finchley, N., August 18th, 1925.

Obituary.

WALTER CARLESS SWAYNE, M.D., B.S. LOND., M.D., CH.B. BRISTOL,

PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF BRISTOL; CONSULTING OBSTETRICIAN AND GYNÆCOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

THE sudden death of Walter Carless Swayne occurred on August 8th at the age of 63, under particularly painful circumstances, at Sellack, near Hereford, at the residence of his son-in-law, Mr. R. D. Wreford-Brown. It appears that Dr. Swayne and his son had joined the family of his daughter and son-in-law, and that about 1 o'clock in the morning Mr. Wreford-Brown, who was gassed at Cambrai when in the Welsh Guards, became suddenly demented. He roused the sleeping household by firing a revolver out of his wife's bedroom window under the delusion that the house was gassed, and then entered his father-in-law's bedroom and shot him in the abdomen. Dr. Swayne's son, groping in the darkness, disarmed the assailant, but Dr. Swayne died a few hours later. He was in the full activity of practice as the leading consulting obstetric surgeon in Bristol and the West of England, and this tragic end to his career has caused profound sorrow to the whole neighbourhood, and especially to his colleagues and patients by all of whom he was greatly esteemed.

Walter Carless Swayne, the eldest son of Mr. R. A. Swayne, of Tillington Court, Hereford, one of a family of seven sons and seven daughters, was born at Mathon, near Malvern, in 1862. He was educated at King Edward's School, Birmingham, and began his professional life by entering the Bristol University College and attending the General Hospital. He at Bristol resided with his well-known uncle, Dr. Joseph Griffiths Swayne, till in 1880 he went up to Guy's Hospital for the completion of his clinical work. After taking the double qualification of the Colleges and graduating M.B. at the University of London with honours in forensic medicine, he became resident obstetric physician under Dr. Galabin and Dr. P. Horrocks. In 1891 Swayne was appointed obstetric physician at the Bristol Royal Infirmary with the charge of six beds and an out-patient clinic. He threw himself into the work and organisation of this department with the zeal that characterised everything that he set his hands to. As time went on he so developed the restricted department till he at length evolved one of the most highly equipped obstetric and gynæcological clinics in the United Kingdom, with separate wards for lying-in cases and gynæcological operations, an extensive extern lying-in department, a large out-patient clinic, and an antenatal clinic.

He took the M.D. degree in 1894 and in the meanwhile he had been appointed Professor of Obstetrics at the University College, and was continued in this post when the University was incorporated in 1909, becoming the first professor in the chair of Obstetric Medicine. As a teacher he attracted a large following and enjoyed a high reputation as a consultant. He took the ad eundem degrees of M.D., Ch.B., and was enthusiastic in fostering a corporate spirit and in upholding the rights of graduates in Convocation, and furthermore was conspicuous in the movement to form an active graduates' association. It was largely due to his initiative that the M.Ch. is granted in obstetrics at Bristol and nothing proves more strikingly his originality than the plan of making an operation by candidates for the Mastership a part of the test for the highest degree conferred in the specialty. Without being a prolific writer he made many valuable contributions to the Bristol Medico-Chirurgical Society's Transactions and to other scientific journals. He contributed also to Latham and English's "System of Treatment," while he edited the eleventh edition of his uncle, Joseph Griffith Swayne's, well-known "Obstetrical Aphorisms." He undertook this task in response to requests so numerous as to make it clear that there was still a place which the re-issue of this popular little work could fill with advantage, and he accomplished the revision successfully, retaining the original form of the work, while rendering it valuable to modern students.

As Major Swayne, R.F.A. (T.), he will be well remembered by a very large number of those serving in the late war. When he first went to Bristol he joined the Bristol Volunteer Artillery Corps; he was nick-named "Bombardier Dick" in recognition of his military enthusiasm, and induced many other students and friends to join, and for his 20 years' steady service he was awarded the V.D. On the outbreak of war in 1914 he had much to do with the initiation of the Bristol University O.T.C., of which he was placed in command. He then threw up all professional ties and became a soldier. He raised the third line of the South Midland R.F.A., proceeding later to the camp at Churn and at Bulford. As an administrative officer he was conspicuously successful; never flinching from the hardships which he had cheerfully undertaken, he was beloved by the men under him. The refusal by the War Office to send him on service abroad was a great disappointment to him, but his none too robust health and his age made the decision reasonable and the work which he rendered at home was admirable. Towards the close of his administrative career he was appointed to the command of a battery of the New Zealand Artillery on Salisbury Plain, which he conducted overseas to France. Five years of military work away from home was a strain which told heavily but never lessened his enthusiastic activities when at the end of the war he resumed his work as professor of obstetrics and his charge of the department at the Royal Infirmary. In recognition of his self-sacrificing devotion to the military service of the country the committee of the Bristol Royal Infirmary extended the tenure of his post at the Royal Infirmary beyond the usual age-limit.

His athletic achievements in youth were considerable and he played for Guy's Hospital at Rugby football and was in the hospital rowing four. Fishing was his hobby in later years, and he was an expert with the dry fly and well known on the Monnow. He was Past Master of St. Vincent's Lodge, and had held office in the higher orders of Masonry. In 1894 he married Louisa Margaret, daughter of the late Rev. R. F. Heath, by whom he had three daughters and a son. A devoted Churchman, a loyal colleague, and ever a sympathetic friend in trouble alike to rich and poor, the death of Walter Swayne is deeply regretted by the medical profession; for his widow and children we sympathise profoundly in their grievous loss.

CHARLES LLOYD TUCKEY, M.D. ABERD.

Dr. Charles Lloyd Tuckey, who died at his house in Eastbourne on August 12th aged 70, had retired from practice and had been in poor health for the past 12 years, but continued to the end his interest in psychotherapy and in psychical research for which he was well known. His father, a medical graduate of Trinity College, Dublin, practised at Canterbury, and Lloyd Tuckey was educated at the King's School and later at King's College, London, and at the University of Aberdeen, whence he graduated M.B., C.M. in 1875, taking the M.D. in 1884. Early attracted to treatment by suggestion he studied hypnotism in 1888 under Liebault at Nancy, and may be regarded as the pioneer of hypnotic therapy in England, being closely followed by the late Dr. Milne Bramwell. Lloyd Tuckey started this work in London in 1878, and at his consulting-rooms in Green-street and Upper Brook-street, W., demonstrated his methods to medical men freely. His success in treatment was helped by his personality, for he was a man of great kindness, wide culture and literary ability, handsome presence, and sympathetic manner. He was a frequent contributor on his subjects to the medical journals and literary reviews, articles from his pen appearing in THE LANCET, *Brain*, *Practitioner*, and the *Nineteenth Century*, while his book, "Treatment by Hypnotism and Suggestion," now in the seventh edition, brought him international recognition. As the cases in this book show, he was frequently successful in the treatment of alcoholism. He was one of the founders of the Society for Psychical Research, and was for many years a member of the council of that body, of which he was afterwards elected an honorary member. His retirement from practice took place at a time when the present psychotherapeutic measures were coming before the profession, and though interested in the developments he was chary of expressing an opinion as to their remedial values after the opportunities of personal clinical trial had gone from him.

Late in life he married Beatrice Mary, daughter of the late Robert Wood Marsland, a London solicitor, who nursed him with devotion during his long illness.

DONATIONS AND BEQUESTS.—The late Mr. Walter Thomas Fremlin, of Milgate Park, Maidstone, left by will £1000 to St. Thomas's Hospital, £300 to the East Kent General Hospital, Maidstone, and £500 to the Kent County Ophthalmic Hospital.—Mr. John Douglas Oliver, of Morpeth, bequeathed £3000 to the Morpeth Cottage Hospital and District Nursing Association.—Colonel John Chadwick Barlow, M.V.O., J.P., of Bury and Darley Dale, Yorkshire, a director of the Bleachers' Association, Ltd., left the residue of his property, amounting to nearly £300,000, to be applied within 21 years of his decease for such charitable purposes within the United Kingdom of Great Britain and Ireland, India, or any British State, Colony, or Dependency as his executors in their absolute discretion should think fit, stating "my desire being that the same shall not be utilised for sectarian or party political purposes, and that they shall have regard to such charitable purposes as I have been interested during my lifetime."—The £600 damages recently awarded to them in the High Court for libel and slander has been awarded by Messrs. J. Lyons and Co., Ltd., to the following charities: the London Hospital £200, Paddington Green Children's Hospital £200, West London Hospital £150, and £50 to the Parent Hospitals of Shropshire and the Border Counties.—On "Alexandra Day" in Liverpool the total sum realised on June 20th was £5670, and of this sum the Liverpool Child Welfare Association received £1596, the Royal Liverpool Children's Hospital £1111, and the Royal Liverpool Children's Hospital, Heswall Branch, £489.—Mrs. Ada Ellen Robertson, of Kensington, W., who left £15,020, apart from a small annuity, practically gave all other of her property to the Hospital for Sick Children, Great Ormond-street.

Medical News.

Post-Graduate Courses in Tuberculosis.—The following courses have been arranged by the Joint Tuberculosis Council: (1) A fortnight's course in the pathology and bacteriology of tuberculosis, conducted by Dr. Roodhouse Gloyne at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, from Monday, Sept. 21st, to Saturday, Oct. 3rd. The class will meet in the mornings or in the afternoons according to arrangement. Class limited to six members. (2) A course in non-pulmonary tuberculosis beginning Monday, Sept. 28th, ending Saturday, Oct. 3rd. Monday, Sept. 28th, at Heatherwood Hospital, Ascot (charabancs from and to London arranged).. Tuesday, Sept. 29th, at Queen Mary's Hospital, Carshalton. Wednesday, Sept. 30th: Morning, diseases of the skin department, London Hospital; afternoon, the Royal College of Surgeons, Lincoln's Inn-fields. Thursday, Oct. 1st: Morning, diseases of the skin department, London Hospital; afternoon, All Saints Hospital for Genito-Urinary Diseases. Friday, Oct. 2nd, and Saturday, Oct. 3rd, the Wingfield Orthopædic Hospital, Oxford. The class will be limited to 30 members. Early application should be made to William Brand, acting Hon. Secretary, 19, Brunswick-square, Camberwell, S.E. 5, who will supply all further particulars.

The Spahlinger Treatment.—Mr. Spahlinger has returned to Geneva to prepare a sufficient quantity of vaccine and serum to immunise a number of calves, as arranged with the Committee of Agriculturists and Veterinary Surgeons which has been formed at Crewe. These tests and controls are to take place in October. The animals are already being selected, and it is expected that Mr. Spahlinger will come to Crewe to make the injections. The results will be observed by a committee of agriculturists and veterinary surgeons, with whom will be associated the Agricultural Committee of the House of Commons, and a representative of the Minister of Agriculture. In the meantime the production of further supplies of vaccine and serum for human beings will be temporarily suspended.

Middlesex Hospital.—The recently issued report for 1924 records that owing to the closing of two wards there was a diminution of 364 in the number of in-patients admitted. Nevertheless, 5188 in-patients were treated. Their average weekly cost was £4 1*s.* 1*d.*, an increase of 2*s.* 3*d.* upon the preceding year. At 38,259 there was an increase of 2440 in the total of in-patients. Grateful note is made of the steady growth of the St. Marylebone Associated Hospitals' League, with a membership of about 20,000, which yielded during the year a total of £2748. A warm tribute is paid to the services of Dr. Campbell Thompson, physician to the department of nervous diseases and lecturer in neurology, upon his resignation from the active staff after an association of 36 years as house physician, dean of the medical school, and in the department of nervous diseases. Attention is drawn to the importance of endowing the professorial chairs attached to the hospital's medical school; of these seven chairs only three have yet been endowed. The period of training for nurses and probationers has been increased from three to four years, but the question of establishing a nurses' preliminary training school has been postponed pending the provision of permanent accommodation. The report of the Cancer Charity of the hospital shows that 712 patients were admitted, an increase of 79, and that the percentage of occupied to available beds was very nearly 95 per cent. There is thus practically no bed-wastage. The rebuilding fund now exceeds £200,000.

Harrogate Royal Bath Hospital.—At this hospital of 150 beds, also styled the National Hospital for Rheumatic Diseases, a new laboratory was opened by Princess Mary, Viscountess Lascelles, on August 10th, when Lord Harewood, the patron, presided over a large meeting in the main hall of the hospital, and pointed out that £5500 were still required to make up the £12,000 appealed for last year. That appeal was for a centenary fund for further equipment of the hospital with adequate accommodation—e.g., for additional nursing staff, surgical, radiological, and dental departments. The new laboratory, which cost £3500, may demand an additional £1000 for equipment, towards which £500 has been subscribed by Sir Edward Brotherton, Bart., while £1000 has been presented by the hon. treasurer of the hospital, Mr. Walter Freeman, as the nucleus of an endowment fund for laboratory purposes.

After Princess Mary had declared the new laboratory open, a short address was given by Prof. Arthur Hall, in which the necessity in medicine for distant vision was emphasised, an important feature of such vision being the furnishing of adequate facilities for laboratory work. After the votes of thanks to Her Royal Highness, Dr. G. L. Kerr Pringle, senior physician to the hospital, drew the attention of the audience to the widespread crippling caused by the group of chronic rheumatic diseases, and the justification for more determined efforts in research.

Princess Mary then inspected the new building, where various aspects of the work of the laboratory were demonstrated by Dr. Sinclair Miller and Dr. F. B. Smith, the pathologists to the hospital. Hitherto this branch of work has been carried on with very limited facilities and accommodation. The new building comprises a waiting-room, a consulting-room, four workrooms for bacteriology and chemistry, a preparation-room, and a cleansing-room, and represents the first step in materialisation of a scheme of development which should make the equipment of the hospital as adequate as that of any hospital in the kingdom. There is now at this hospital ample opportunity both for routine investigation of individual patients and for organised research into the problems involved in the ætiology and treatment of chronic arthritis and allied conditions which still remain obscure.

Death of a South African Practitioner.—The death on July 19th is announced of Dr. Peter Christian de Wet, of Cradock, Cape Province, where he had practised for 34 years. He was the local medical officer of health and had been largely concerned with the establishment of the Cradock Hospital 25 years ago.

Keighley's New Water-supply.—The Marquess of Hartington on August 11th performed the inauguration ceremony of the Keighley Corporation's new Sladen Valley waterworks. The scheme was begun in 1910, and has cost £570,000. The new waterworks will add an available supply of a million gallons a day in addition to the existing 1,600,000 gallons a day from the Watersheddles reservoir. The gathering-ground of the new supply comprises an area of 1080 acres.

The late Dr. A. W. Atkinson.—Arthur William Atkinson, M.B., Ch.B. Edin., died at his residence in Crewe on August 6th from pneumonia. Born in Crewe in 1881, he was the youngest son of the late Dr. James Atkinson, first mayor of Crewe. He studied at the University of Edinburgh and at Heidelberg, graduating M.B., Ch.B. Edin. in 1906, and later obtained the certificate with distinction of the London School of Tropical Medicine. He served with great credit in the Boer War, and for some time was medical officer on the West African Medical Staff on the Gold Coast. On the death of his brother, Dr. J. R. Atkinson, he gave up his Government appointment to take up practice in Crewe. A keen lover of sport, he was also a prominent Freemason. Dr. Atkinson, who leaves a widow and a daughter, was highly appreciated as a family physician.

Manchester's Sewage Disposal.—On August 12th a Ministry of Health inquiry was held in the Manchester Town Hall into the application of the corporation to borrow £465,000 for an extension of the sewage disposal scheme. The cost of the extension will be equal to 2¼*d.* in the rates. The proposed improvements are designed to meet drainage demands for the next 50 years. Additional facilities will be provided for the disposal of sludge, which at present is taken by boat down the Ship Canal and dumped into the sea, and over 200,000 tons a year are disposed of in this way. It was stated that later it was hoped that the sludge would be so treated as to form a product for agricultural purposes.

Appointments.

Mortis, R. H., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon, Hertford County Hospital.

Muir, T. J., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Pickering District (North Riding).

Vacancies.

For further information refer to the advertisement columns.

Birmingham University.—Lecturer in Bacteriology. £450.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. £120.

Bootle Borough Hospital.—H.S. At rate of £125.

Brighton, New Sussex Hospital.—H.S. £50.

Bristol General Hospital.—H.P.'s, H.S., &c. Each at rate of £80.

Bristol Royal Infirmary.—Sen. Res. M.O. At rate of £200. H.P.'s, H.S.'s, &c. At rate of £80. Dental S. At rate of £116.

Canterbury, Kent and Canterbury Hospital.—Hon. S. to Ear, Nose, and Throat Dept. Also Third Res M.O. At rate of £125.
Devonport, Royal Albert Hospital.—H.S. £150.
Dumfries, Crichton Royal Mental Hospital.—Asst. P. £350.
Glamorgan County Mental Hospital, Bridgend.—Temp. Asst. M.O. At rate of £300.
Gloucester Institution and Infirmary, Great Western-road.—M.O. £150.
Hertford County Hospital.—H.P. At rate of £160.
Jersey General Hospital and Poor-law Infirmary.—Res. M.O. £200.
Liverpool, Royal Southern Hospital.—Hon. Asst. P.
Manchester, Monsall Hospital for Infectious Diseases.—Second Asst. M.O. £275.
Manchester Royal Children's Hospital, Pendlebury.—Asst. M.O. At rate of £150. Res. Surg. O. At rate of £80.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Medical Society of London.—Secretary.
Plymouth Borough.—Asst. M.O.H. £600.
Poplar Hospital for Accidents, East India Dock road, Poplar, E.—Sen. Res. O. £200.
Preston County Borough.—Asst. Sch. M.O. £600.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Asst. Res. M.O. At rate of £80.
Royal Eye Hospital, St. George's Circus, S.E.—H.S.
Royal Free Hospital, Gray's Inn-road, W.C.—Obstet. Asst. At rate of £100.
Salop County Council.—Asst. M.O. £600.
Southampton, Borough Isolation Hospital.—Res. M.O. £300.
Staffordshire Mental Hospital, Cheddleton, Leek.—Jun. Asst. M.O. £350.
Stockport Infirmary.—Two Res. H.S.'s. Each £175.
Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.
Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of Chest.—Jun. Res. M.O. At rate of £250.
West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: East Grinstead, Sussex; Petersfield, Hants; Colwyn Bay, Denbigh.

Births, Marriages, and Deaths.

BIRTHS.

DE MOWBRAY.—On August 15th, at Grosvenor House, Lymington, Hants, the wife of Ralph M. de Mowbray, F.R.C.S., of a son.
EVANS.—On August 13th, at Glanfraed, Brundall, Norwich, the wife of Dr. Henry W. Evans, of a son.
FRASER.—On August 9th, at Garlands, Redhill, the wife of Dr. M. W. Fraser, W.A.M.S., of a daughter.
WOOLER.—On August 8th, at St. John's House, Cleckheaton, Yorks, the wife of Dr. E. W. Nowell Wooler, of a daughter.

MARRIAGES.

CHARLES—FISHER.—On August 6th, at St. Michael and All Angels' Church, Butcombe, Somerset, John Roger Charles, M.D., F.R.C.P., to Hilda Mary Fisher.
KITCHIN—LANDER.—On August 12th, in London, Derek Harcourt Kitchin to Mary Kathleen Forsaith Lander, M.Sc., M.B., B.S.

DEATHS.

ALEXANDER.—On August 19th, at Kingsdown-road, Epsom, Thomas Anderson Alexander, M.D., in his 67th year.
HULKE.—On August 15th, at Admiralty House, Deal, Frederick Backhouse Hulke, J.P., M.R.C.S., L.R.C.P., aged 65 years.
WARNER.—On August 15th, at Clacton-on-Sea, after a long illness contracted during the war, Cuthbert Warner, B.A., M.B., B.Ch., late surgeon in the Royal Navy.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 24th, to SATURDAY, August 29th.—ALL SAINTS HOSPITAL, Vauxhall Bridge-road, S.W. Clinical demonstrations Wednesday evening, Thursday afternoon and evening, and Saturday afternoon. Wed., 2 P.M., Mr. J. C. Ainsworth Davis on Tuberculin in the Treatment of Urological Tuberculosis.—QUEEN MARY'S HOSPITAL, Stratford, E. Intensive Course in General Medicine, Surgery, and the Special Departments. First week as per syllabus. Morning and afternoon sessions. Fee £2 2s. for week or £3 3s. for two weeks.

Notes, Comments, and Abstracts.

NEW REGULATIONS FOR PRESERVATIVES IN FOOD.

CERTAIN new regulations under the Sale of Food and Drugs Acts have been laid down and circulated to town clerks, clerks to councils, and port sanitary authorities, based on the recommendations of the Departmental Committee on the *Use of Preservatives and Colouring Matters in Food.* The Regulations provide for the prohibition of the importation and sale of articles of food to which preservatives and other specified substances have been added, and in particular an important section deals with food importations. The enforcement of the edict with respect to meat and fish is to be left to the local authorities, who are not precluded from taking action with regard to other articles, though care has been taken in the Regulations to avoid any duplication of jurisdiction as between them and officers of Customs and Excise.

One of the recommendations of the Departmental Committee was, that any prohibitions or limitations imposed by Regulations should bind the courts in proceedings taken under the Sale of Food and Drugs Acts. In this way the Committee went on to say: "Traders and the public generally would know what was permissible and what was not, and there would be no conflict of expert evidence on the question whether the amount of preservative or colouring matter was or was not injurious to health. The only point at issue would normally be whether the preservative or colouring matter found in the food, or the amount of it, was in contravention of the Regulations." The Departmental Committee recommended a change in the law in this direction, and the Minister of Health is entirely in agreement with the view of the Committee, but it has not been found practicable to introduce legislation to give effect to the recommendation. The Minister commends the matter, however, to the consideration of local authorities and suggests that proceedings should not be taken under the Sale of Food and Drugs Acts in respect of the addition of preservatives to food except where such addition would be contrary to the provisions of the Regulations. "In this connexion," the Minister's communication runs, "local authorities will no doubt have regard to the fact that in conformity with the recommendation of the Committee, the Regulations have been framed so as to allow time for the adjustment of methods and processes and the clearance of existing stocks, before they come into operation."

No Regulation is made concerning the question which has arisen as to the power to give incriminated persons an opportunity to furnish explanations, the matter being left to the discretion of the local authorities. But the local authorities are reminded that they have power instead of, or in addition to, taking proceedings against a retailer, to take proceedings against the manufacturer or wholesaler by whom the article was previously sold. It is suggested that this provision might be used with advantage in many cases where an article of food is sold in a sealed container bearing the name and address of the manufacturer or of the wholesale dealer responsible for its distribution.

The Regulations come into force on Jan. 1st, 1927.

Appended are two schedules. The first enumerates (1) the articles of food which may contain preservative and the nature and proportion of the preservative in each case; and (2) the colouring matters which may not be added to articles of food. In these forbidden sophistications are found the colouring matters derived from antimony, arsenic, and other metals the use of whose salts is found perilous. It will be seen from the first part of this schedule that sulphurous acid and benzoic acid will be the only preservatives that can be employed legally after Jan. 1st, 1927, and undoubtedly the exclusion of boron will give rise to discussion. The Regulations must be welcome, for the simple reason that they will baffle the ingenuity of those who are still able to disguise the presence of putrefaction in our foodstuffs, and in this way to escape the necessity of cleanly storage and transport and careful handling; but it will be seen that considerable difficulty will arise unless new arrangements are made both in shops and households with respect to the protection of perishable material. Under this large abolition of chemical preservatives, though no one can regret the unqualified veto upon dangerous minerals and formaldehydes, there will be great difficulty during summer periods of protecting many articles of food from putrefaction, save in great establishments where cold-storage plants are in existence. As Mr. P. N. Panton has written in the *Times* this week, "We shall have to ensure a more rapid carriage of foodstuffs, a greater cold-storage accommodation, and an installation of refrigerators in the home as widely distributed as in the United States."

The second schedule gives instructions for the labelling of articles of food containing preservatives, and also for the labelling of the preservatives themselves.

THE FIRST SCHEDULE.

PART I.—*Articles of Food which may contain Preservative and Nature and Proportion of Preservative in each case.*

The articles of food specified in the first column of the following table may contain the preservative specified in the second column in proportions not exceeding the number of parts (estimated by weight) per million specified in the third column :—

Food.	Preservative.	Parts per million.
1. Sausages and sausage-meat containing raw meat, cereals and condiments	Sulphur dioxide	450
2. Fruit and fruit pulp, not dried :—		
(*a*) Strawberries and raspberries..	,,	2000
(*b*) Other fruit	,,	1500
3. Dried fruit :—		
(*a*) Apricots, peaches, nectarines, apples, and pears	,,	2000
(*b*) Raisins and sultanas	,,	750
4. Unfermented grape-juice and non-alcoholic wine made from such grape-juice if labelled in accordance with the rules contained in the Second Schedule to these Regulations	Benzoic acid	2000
5. Other non-alcoholic wines, cordials, and fruit juices, sweetened or unsweetened	Either sulphur dioxide or benzoic acid	350 600
6. Jam (including fruit jelly prepared in the way in which jam is prepared, but not including marmalade made from citrous fruits) ..	Sulphur dioxide	40
7. Candied peel	,,	100
8. Sugar (including solid glucose) ..	,,	70
9. Corn syrup (liquid glucose) ..	,,	450
10. Gelatine	,,	1000
11. Beer	,,	70
12. Cider	,,	200
13. Alcoholic wines	,,	450
14. Sweetened mineral waters	Either sulphur dioxide or benzoic acid	70 120
15. Brewed ginger beer	Benzoic acid	120
16. Coffee extract	,,	450
17. Pickles and sauces made from fruit or vegetables	,,	250

PART II.—*Colouring Matters which may not be added to Articles of Food.*

1. *Metallic Colouring Matters.*—Compounds of any of the following metals : Antimony, arsenic, cadmium, chromium, copper, mercury, lead, and zinc.

2. *Vegetable Colouring Matter.*—Gamboge.

3. *Coal Tar Colours.*

Number in colour index of Society of Dyers and Colourists, 1924.	Name.	Synonyms.
7	Picric acid.	Carbazotic acid.
8	Victoria yellow.	Saffron substitute ; dinitrocresol.
9	Manchester yellow.	Naphthol yellow ; martius yellow.
12	Aurantia.	Imperial yellow.
724	Aurine.	Rosolic acid ; yellow coralline.

THE SECOND SCHEDULE.

Labelling of Articles of Food containing Preservative and of Preservatives.

1. The articles of food containing preservative to which the Rules as to labelling set out in this Schedule apply are sausages, sausage-meat, coffee extract, pickles and sauces, and (where the proportion of benzoic acid exceeds 600 parts per million) grape-juice and wine.

2. (1) Where any of the said articles of food contains preservative it shall bear a label on which is printed the following declaration or such other declaration substantially to the like effect as may be allowed by the Minister:—

> (a) CONTAIN(S)
> PRESERVATIVE.

(2) The declaration shall be completed by inserting at (*a*) the word "This" or "These," followed by the name of the food as used in paragraph 1 of this Schedule.

(3) In the case of grape-juice or wine to which these Rules apply there shall be added to the declaration the words "*and is not intended for use as a beverage.*"

3. (1) An article sold as a preservative shall bear a label on which is printed the following declaration or such other declaration substantially to the like effect as may be allowed by the Minister :—

> THIS PRESERVATIVE CONTAINS
> (a) PER CENT. OF SULPHUR DIOXIDE.

(2) Where the article contains benzoic acid the words "Benzoic Acid" shall be substituted for the words "Sulphur Dioxide."

(3) The declaration shall be completed by inserting at (*a*) in words and figures, excluding fractions (e.g., "seventy (70)"), the true percentage of the sulphur dioxide or benzoic acid present in the article.

4. The prescribed declaration shall in each case be printed in dark block type upon a light coloured ground within a surrounding line and no other matter shall be printed within such surrounding line. The type used shall be not less than one-eighth of an inch in height, or, in the case of grape-juice or wine to which these Rules apply, one-sixteenth of an inch in height.

5. The label shall be securely affixed to the article or be part of or securely affixed to the wrapper or container, and in any case shall be so placed as to be clearly visible. If the article bears a label containing the name, trade mark, or design representing the brand of the article or the name and address of the manufacturer or dealer the prescribed declaration shall be printed as part of such label.

6. No comment on or explanation of the prescribed declaration (other than any direction as to use in the case of a preservative) shall be placed on the label or on the wrapper or container.

THE PREVALENCE OF VENEREAL DISEASE.

THERE is no compulsory notification of venereal cases, so that the figures recently circulated as to the numbers of cases of venereal disease dealt with for the first time at treatment centres in England and Wales during each of the years from 1919 to 1924 are of interest.

Year.	Cases.*	Attendances.†	Year.	Cases.*	Attendances.†
1919	82,797	1,002,791	1922	56,347	1,500,568
1920	85,531	1,488,514	1923	55,945	1,605,617
1921	66,820	1,612,592	1924	54,380	1,645,416

* No. of cases dealt with for the first time at treatment centres in England and Wales during the year and found to be suffering from venereal disease.

† Total No. of attendances at treatment centres during the year.

The total number of attendances at the centres during each of those years does not bear out the pessimistic estimates that have been very usual.

CRESER'S PATENT DEODORISER AND DISINFECTANT CONTAINER.

WE have received from Mr. A. T. Creser, of 3, Manor Park, Richmond, Surrey, an apparatus designed for use in deodorising and disinfecting w.c.'s, which seems to possess decided advantages both of efficiency and economy. It consists of a perforated non-rustable metal cylinder containing a disinfectant in a solid but soluble form. The cylinder is simply and easily fixed under the rim of the w.c. pan, and in the track of the high-velocity water which washes out a certain amount of the disinfectant contained in the cylinder. On the rush of water ceasing, the drainage of the container automatically gives to the water in the pan, after the valve is closed, a strong solution of the disinfectant, which remains in the pan until the water is again set flowing. The apparatus can be refilled in less than 15 seconds, each refill will last from two to three months, and the cost of usage is approximately ½*d.* a week.

AFTER 50 years at 1, Fenchurch-avenue, E.C. 3, Messrs. F. W. Berk and Co., Ltd., the well-known chemical manufacturers, are removing their head offices on Monday, August 24th, to larger premises at 100, Fenchurch-street, London, E.C. 3.

STUDENTS' GUIDE—SESSION 1925-1926.

The scheme upon which the Students' Number of The Lancet is constructed will make it easy, we hope, for all who consult it to find what they seek. The General Council of Medical Education and Registration *is the controlling authority of all the medical and dental education of the country, and its responsibility for* the upkeep of the Medical Register and for the maintenance of the examination standard is first explained.

But the student has to be taught as well as examined, and as the systems under which instruction can be obtained do not conform to one pattern, the various curricula are described in detail, and under their respective headings the necessary information will be found concerning the facilities for medical study offered at the different teaching centres of the United Kingdom. The regulations for the examinations, both *preliminary and professional, at these centres are set out so that the student desiring to obtain a* medical degree from any university, or a diploma from any medical corporation, may ascertain the course of clinical instruction and the conditions under which submission for examination has to take place. The metropolitan medical schools and hospitals are grouped under the University of London, of which they are constituent bodies, although their educational opportunities are offered to students of other universities as well as to those seeking the qualifications of the medical corporations. A similar plan is adopted in dealing with the provincial universities, the hospitals in direct connexion with which are described with the universities; the hospitals may not be official schools of the universities, but they supply an integral section of the teaching required.

Upon securing degrees or diplomas admission to the Register follows, and greater education begins. The prudent young doctor already knows what he or she desires to make the next step, and there is a large range of choice displayed. The inducements to enter one of the Services should prevail more than they have done of recent years. An account is given of the conditions under which commissions can be obtained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial and other Medical Services.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Powers, Duties, and Constitution of the General Medical Council.

The powers and duties of the *General Medical Council*, or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of The Lancet. It is first a registering body: no person, even though his qualifications have been obtained by *examination*, is a legally qualified medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that medical education reaches an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives. There are also three additional members appointed by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom (see p. 470).

The President of the General Council is Sir Donald MacAlister, and the sitting members of the Council are enumerated in the Medical Register.

The Educational Curriculum.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following are the General Medical Council's Regulations in regard to the registration of medical students which came into force on Jan. 1st, 1923.

Registration of Medical Students.

1. Subject to such exceptions as the Council may from time to time allow, every medical student, at the commencement of his studies, should be registered under the conditions hereinafter set forth.

2. Before registration every candidate should produce evidence that he has attained the age of 17 years.

3. The minimum standard of General Education required is that of University matriculation or entrance examination in the Faculties of Arts or Pure Science.

4. Before registration as a student every applicant should be required to have passed an approved examination in general education, and, in addition thereto, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies.

5. A student who has diligently attended an approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may be admitted to the professional examination in elementary biology immediately after his registration as a student.

6. The commencement of the course of professional study recognised by any of the licensing bodies should not be reckoned as dating earlier than 15 days before the date of registration.

7. Every person desirous of being registered as a medical student should apply to the registrar of the division of the United Kingdom in which he is residing, according to a prescribed form, copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Medical Council; and should produce or forward to the registrar evidence that he has attained the age of 17 years, that he has passed a preliminary examination in general education recognised by the General Medical Council, and, in addition, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies, and that he has commenced medical study.

Regulations which the Council has prescribed for the maintenance of the register of medical students:—

1. It shall be delegated to the Education Committee to prepare and issue from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the General Medical Council.

2. The Council has recognised the undernoted university examinations, subject to the conditions specified below: viz., at Oxford University, Responsions; at Cambridge University, the Previous Examination; at the Scottish Universities, the Preliminary Examination; and the Matriculation Examination at the Universities of Birmingham,

Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, and Wales.

3. The conditions prescribed by the Council are:—(1) The standard of the examination shall not be lower than that of the University Matriculation Examinations in the Faculties of Arts and Pure Science. (2) The certificate shall bear evidence that the candidate has passed in the following subjects, viz.:—(*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) An additional subject or subjects, as required by the regulations of the particular examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose.

4. Subject to the conditions specified above (Section 3, Subsection (2)), the Council will recognise all examinations conducted by recognised authorities in Great Britain accepted by one or more of the above-named Universities as equivalent for purposes of Matriculation to an examination named in the preceding list (Section 2). Bristol University: Higher School Certificate Examination; Schools Certificate Examination. Cambridge Local Examinations and Lectures Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Senior Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: General School Examination; Higher School Certificate Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

5. The Council will continue to recognise examinations conducted by educational bodies other than those (referred to in Section 4) directly recognised by the Universities of Great Britain. Recognition will not be extended under this section to any examination unless the Council is satisfied (1) that in scope and standard it is equivalent to a recognised Matriculation Examination of a British University, and (2) that it fulfils the conditions specified by the Council (Section 3, Sub-section (2)). Such examinations are:—The College of Preceptors (England): Senior Certificate. The Educational Institute of Scotland: Preliminary Medical Certificate.

Examinations in Ireland.—6. Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, the Matriculation Examinations of the National University of Ireland and the Queen's University of Belfast, the Preliminary Examination of the Irish Royal Colleges of Physicians and Surgeons, the Leaving Certificate of the Intermediate Education Board of the Irish Free State, and the Senior Leaving Certificate of the Ministry of Education of Northern Ireland, and all examinations accepted by one or more of the Universities as equivalent for purposes of entrance or Matriculation, to the above-named examinations.

7. The Council will recognise the Final Examinations for Degrees in Arts and Science of any University of the United Kingdom or of the British Dominions.

Colonial Examinations.—8. Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise all examinations of Colonial Universities which are accepted by one or more of the British Universities as equivalent, for purposes of Matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

A copy of the Medical Students Register prepared by each of the Branch Registrars is transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who supplies an alphabetical list of all students registered in the preceding year to each of the licensing bodies in the United Kingdom, and to each of the several medical schools and hospitals.

All applications for special exceptions to the foregoing regulations as to registration should be addressed to the Registrar of the General Council.

Lists of Universities (including their Colleges and Medical Schools) and Schools of Medicine at which Medical Study may be Commenced in the United Kingdom.—1. Universities (including their colleges): Aberdeen University; Belfast, Queen's University; Birmingham University; Bristol University; Cambridge University; Dublin University (including Trinity College); Durham University (including the Durham College of Medicine); Edinburgh University; Glasgow University (including Queen Margaret College); Ireland, National University (including University College, Cork; University College, Dublin; University College, Galway); Leeds University; Liverpool University; London University (including the following Schools and Colleges: St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College, King's College Hospital, London Hospital, St. Mary's Hospital, Middlesex Hospital, St. Thomas's Hospital, University College, Westminster Hospital, London (Royal Free Hospital) School of Medicine for Women; Bedford College, Royal Holloway College; Manchester, Victoria University; Oxford University; St. Andrews University (including University College, Dundee); Sheffield University; Wales, University of (including University College of Wales, Aberystwyth); University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; Welsh National School of Medicine, Cardiff; University College, Swansea. 2. Schools of Medicine Recognised by the Licensing Bodies:—Dublin: Royal College of Surgeons, Schools of Surgery; Edinburgh: School of Medicine of the Royal Colleges; Glasgow: Anderson's College, St. Mungo's College.

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1.

THE IRISH FREE STATE AND THE GENERAL MEDICAL COUNCIL.

On August 15th the announcement was made by the Government of the Irish Free State that the Executive Council had decided "not to seek the continuation of the United Kingdom arrangement whereby the medical profession in Ireland with certain representations is controlled by the British General Medical Council."

When the autonomous Free State was set up in January, 1922, early negotiations with the Provisional Government procured the remaining in force of the existing arrangement as to the Medical Acts, unless and until the Irish Free State saw fit to legislate for practitioners within its own area. But the Free State making no move, it was indicated from the General Medical Council that this should be done explicitly if it was wished to preserve the connexion. Last year a Bill was introduced into the Free State Parliament authorising the General Medical Council to continue jurisdiction for a period of one year. This Bill was passed by the Senate of the Free State on Feb. 23rd, 1925, from which date it became effective for the indicated period, but there was opportunity given for extension of the interim measure. At a conference held in April of this year in Dublin, the Minister of Local Government and Public Health of the Free State, in whose department the matter lay, met representatives of the medical profession in the State, when it was urged by the representatives that the existing status should not be disturbed; but the recent decision of the Government of the State is to set up a separate medical register.

If the intention of the Government of the Free State proceeds to action a new Act of Parliament will be required.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THIS University confers two degrees in Medicine, those of *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health and Ophthalmology.*

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany. 2. *Professional.* (*a*) *First Examination:* Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science: Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing the First Examination, the candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a *period of at* least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery and Midwifery at one and the same time.

Before admission to the Second B.M. Examination, the student must produce certificates of having attended laboratory courses in Pathology, Bacteriology and Pharmacology either in Oxford or in a recognised medical school. He must also produce certificates of having acted as Clinical Clerk and Dresser, each for six months, in a medical school approved by the University, of post-mortem clerking, of attendance on Labours, of instruction in Infectious Diseases and Ophthalmology, of proficiency in vaccination and the administration of anæsthetics, and of three academic years of Hospital Practice.

The degree of B.Ch. is granted with that of B.M. after passing the above examinations. The degree of D.M. is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine. The degree of M.Ch. is granted after examination to Bachelors of Surgery in the University who have entered upon their twenty-first term, and who are Members of the Surgical Staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

The examinations for the Diploma in Public Health (see p. 474) in two parts are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology (see p. 473) is held annually in July.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years; the exhibitions vary in value from £30 to £90 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

In addition to the University Lectures and classes the several Colleges provide their undergraduates with tuition *for all examinations* up to the B.A. degree.

In the Radcliffe Infirmary and County Hospital elementary clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology. Post-graduate courses are held at the beginning of October.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1923 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; from the Professors in the several departments of medical science; and from the Dean of the School of Medicine, Department of Medicine, Museum, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY *AND COUNTY HOSPITAL.*—*Courses* of *instruction* are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and *instruction* in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 225 beds.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the ordinary B.A. degree, or an Honours degree by passing a Tripos Examination. The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) General and Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *second* is divided into three parts—viz., (1) Organic Chemistry, (2) Human Anatomy and Physiology; and (3) Pharmacology and General Pathology. The *third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the *third* M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Chir.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Chir.*) the candidate must have passed all the examinations for B.Chir., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Chir.

Diplomas are granted in Public Health, in Hygiene, in Tropical Medicine and Hygiene, in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification. (See p. 472.)

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the M.B. Examinations.

University Prize in Medicine.—The one University Prize in Medicine, the *Raymond Horton Smith Prize* (value £19), is awarded to that candidate for the degree of *M.D.* who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrar, The Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree-conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby; or (*b*) under one or more of the appointed or recognised teachers of the University.

Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine, the Lister Institute of Preventive Medicine, the Maudsley and Bethlem Royal Hospitals are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*); the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University.

The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Tuesday following the third Monday in March and on the second Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, *together* with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year and commences on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Bachelor of Pharmacy.—The Senate has approved the institution of the Degree of Bachelor of Pharmacy (B. Pharm.). The course for this Degree *extends over* three years.

Fees.—Matriculation £2 12*s.* 0*d.* for each entry; at provincial examinations an additional local fee is charged. First examination for Medical Degrees: *£9 9s. for each entry to the entire examination.* For re-examination in one subject the fee is £2 2*s.* Second examination, Part I. £3 3*s.*, repeated on each subsequent entry; Part II. £9 9*s.* for the whole examination. Third examination: £12 12*s.* for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day, except Saturdays, at 1.30 P.M., and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments, are chosen from the students. A residential college is attached to the hospital.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions. Facilities for research work are afforded in the Clinical Units and the Laboratories of the pathological and other departments. *A Vacation Post-graduate Course*, adapted to the needs of general practitioners, is given annually. The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (*c*) and (*d*) are awarded after examination in Latin, Mathematics, and Greek or French or German; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £30 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, 10 guineas, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

Information may be obtained on application to the Dean of the Medical College: Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake Research. Special facilities are available for Post-graduate Research and Study.

---

[1] For Ancillary Metropolitan Medical Schools see p. 437.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining. Special demonstrations are arranged for Post-graduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society. An athletic ground, comprising six acres, has recently been acquired and is now in use.

Women Students.—Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments.

Fees.—Entrance: Primary and Intermediate, 10 guineas; Final, 8 guineas; Annual, £12.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 430 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds. Children's beds are placed in the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the posts (2) of Junior Anæsthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Scholarships and Prizes.—At this school five entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology. This year, in addition to these Scholarships, Exhibitions, each of the value of £10 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85; (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*i*) H. C Johnson Memorial Prize, £19, Practical Anatomy; (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology; (*k*) Clarke Prize, £5; (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

Further information may be obtained from the Dean of the Medical School, Dr. J. A. Torrens.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1724 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 616 beds. The whole of the medical school has been rebuilt during the last 27 years. It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum. Within the grounds of the hospital are situated the residential college, with accommodation for 86 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology and genito-urinary diseases, house physician in the department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, clerks to medical units, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit. There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, *Salomon's Welfare Centre* (for Maternity and Children).

Scholarships.—Six entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1926); (*b*) one Open Arts Scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra; (*c*) one Open Junior Science scholarship for students under 21 years, £100; subjects, any two of the following: Inorganic Chemistry, Physics, and Biology; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended the Preliminary Science Classes at this School (*e*) two open Science scholarships: (1) a War Memorial scholarship of the value of £80, awarded annually in September; (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Professor T. B. Johnston, from whom information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Medical Science) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The department is open to both men and women.

Scholarships.—(*a*) Two Warneford Entrance Scholarships of £30 each for four years. Examination in July, subjects selected from Divinity, Classics, Science. (*b*) Sambrooke Scholarship of £30 for three years. Examination in April or May, subjects selected from Classics, Science. (*c*) Worsley Scholarships: £100 in five annual instalments of £20. (*d*) Rabbeth Scholarship of £20 for best work in first year. (*e*) Second Year Scholarship of £20 tenable for one year. (*f*) Daniell Scholarship of £40 for one year. Awarded on University Honours Examination.

Fees.—Tuition fee of 35 guineas for the first year, £42 per annum for the second and third years, with a materials fee of 4 guineas in the first year, 6 guineas in the second year, 4 guineas in the third year. For prospectus and further information application should be made to the Dean of the Medical Faculty (Professor E. Barclay-Smith), King's College, Strand, W.C. 2.

Dental Course.—The College, in association with King's College Hospital, has instituted courses for the Degree in Dental Surgery of the University of London and for the Dental Diploma of the Conjoint Board.

Fees.—First year (Chemistry and Physics), 20 guineas; second and third years (Anatomy, Physiology, Dental Mechanics, and Dental Metallurgy), 52 guineas per annum. Fourth and fifth years (Hospital), 60 guineas per annum. For prospectus and further information application should be made to the Secretary, King's College Hospital Medical School, Denmark Hill, S.E.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are taught at the Medical School of King's College Hospital, which is situated at Denmark Hill, S.E. 5. The hospital stands in the midst of a large South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 196,211 attendances in the out-patient and casualty departments. Accommodation for 400 beds for in-patients has been built, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physicotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Sixteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Warneford Scholarships, (*b*) Sambrooke Scholarship, (*c*) Rabbeth Scholarship, £20; (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) A Medical Entrance Scholarship in Science, value £50, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4s. and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors; (*l*) two Raymond Gooch Scholarships, £120 each, open to students of British Universities on certain conditions; (*m*) an Epsom College Scholarship, value £50, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London. The Warneford and Sambrooke Scholars are required to take the subjects of the preliminary and Intermediate examinations at King's College, and the final subjects at King's College Hospital.

Dental School.—When the Hospital was built accommodation was provided for a Dental Department. Arrangements have been made for the use of this section, together with additional rooms for Dental Metallurgy, by the Dental School, which was opened in November, 1923, under the direction of Mr. A. Livingston, M.B., Ch.B., Mast. Dent. Surg. A full course is given in coöperation with King's College, and includes arrangements for students who desire to avail themselves of the special provisions of the Dentists Act.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. An athletic ground, over six acres in extent, has been provided for the use of the students on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes"—a hall of residence available for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final Medical subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, *Dean;* Mr. S. C. Ranner, *Secretary of the Medical School*, King's College Hospital, Denmark Hill, S.E. 5.

LONDON HOSPITAL.—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 950 beds, which are in constant use, and is the only general hospital for East London. During last year 17,975 in-patients and 131,969 out-patients received treatment, while 7656 major operations were performed. 36,023 out-patients attended the special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, &c., and the Pediatric, Orthopædic, Venereal, Radiological, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

A Clinical Unit in Medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and coördination of medical research.

To each medical and surgical firm throughout the hospital there is attached a First Assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations. Special entries for medical and surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Union Athletic Ground, 13 acres, is within easy reach of the hospital.

Scholarships and Prizes.—The following is a list of the Scholarships and Prizes:—Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £75, Human Anatomy and Physiology; Buxton Prize, £40, subjects of Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery; Letheby Prizes (2), £26, Chemistry and Chemical Pathology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery; Treves Prize, £15, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £20, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Diseases of Children; K. E. D. Payne Prize, £20, Pathology; and Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of approximately £40,000 permit of financial assistance being given to students and graduates engaged in Medical Research.

Dean: Professor William Wright, London Hospital Medical College, E. 1.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The Hospital and Medical School are situated close to Paddington station (G.W.R.) having on one side a poor district of 500,000 persons, and on the other side the residential districts of Kensington and Bayswater. The hospital contains 288 beds and, by a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals, the teaching facilities extend over 1000 beds. The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has recently been added.

Clinical Facilities.—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognised by the University Grants Committee, St. Mary's being one of the six Medical Schools in London which enjoy this privilege. Lying-in beds have recently been added, and, in addition to this, arrangements have been made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee.

Institute of Pathology and Research.—Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S.

Appointments.—Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and research beds have been instituted. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly-qualified members of the Medical School, including ten salaried posts with salaries varying from £200 to £750 per annum.

Complete Curriculum.—The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Three Entrance Scholarships of the value of £210 each are awarded annually, and two University Scholarships of £200.

Fees.—Composition Fee for entire curriculum (5½ years) £200 in one sum, or £210 by four annual instalments. Composition Fee for Clinical curriculum (2½ years) 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

MIDDLESEX HOSPITAL.—The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electro-Therapeutic department. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electro-Therapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

The Medical School, which includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 80 recognised Teachers, 8 Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are: the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone. Primary F.R.C.S. class will resume in July.

Special classes are held to prepare students for the Intermediate Examinations of the Universities.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. Eight registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, &c.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship for Foundationers or Council Exhibitioners of Epsom College is awarded annually on the nomination of the Headmaster. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5s.; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas. There are also numerous class prizes.

Fees.—The fees are arranged on a basis of an annual payment of approximately £45 for the six years of the curriculum. After six years, if the student is not qualified, the annual fee is £23.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, Musical Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. There are a restaurant and gymnasium in the school buildings, and large athletic grounds at Wembley, with new pavilion. The subscription to the Amalgamated Students' Club is included in the above fees. Full particulars on application to the Dean, Middlesex Hospital Medical School, W. 1.

ST. THOMAS'S HOSPITAL.—This Hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 644 beds. The in-patients last year numbered 10,139, whilst the number of attendances as out-patients, including the casualty and light departments, was 488,600. There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments. An electro-cardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electro-therapy, Phototherapy, Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity Ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments Open to Students after Qualification.—A Resident Assistant Physician, a Resident Assistant Surgeon, and a Resident Anæsthetist are appointed annually at a salary of £200 each per annum. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An Obstetric Tutor and Registrar, an Ophthalmic Registrar (at an annual salary of £50 each), and an Orthopædic Registrar (unpaid) are appointed yearly. Two Senior Resident Casualty Officers (Medical and Surgical) are appointed yearly. Eight Resident Casualty Officers and Anæsthetists are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Fees.—The annual fees are: For each year of study £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following subjects: Anatomy, Physiology, and Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, Medicine, Pathology and Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) Toller Prize, Medicine; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, biennially, Surgery and Surgical Pathology; (*j*) Solly Medal and Prize, biennial, Reports of Cases; (*k*) Sutton Sams Prize, biennial, Report of Cases; (*l*) Bristowe Medal, Pathology and Morbid Anatomy; (*m*) Hadden Prize, Pathology; (*n*) Grainger Testimonial Prize, £31 10s., Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology.

The Dean of the Medical School is Sir Cuthbert S. Wallace, and the Medical Secretary Dr. A. Elliot, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Histology, Physiology, Biochemistry, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health. Research work is undertaken in all departments. The completion of the Institute of Medical Sciences, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study in anatomy, physiology, and pharmacology. In particular might be specified the opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and experimental embryology. Arrangements exist for the close correlation of work in the Institute with University College Hospital and Medical School.

Faculty of Medical Sciences.—Composition Fees.—For the courses required by the University of London. 1. For the First Medical Course, 35 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, and Pharmacology, and to the privileges of the Union Society or the Women's Union Society for two sessions.

For the medical education required by the Examining Board in England: (i) For the course for the Premedical Examination, 35 guineas, entitling to attendance and to the privileges of the Union Society for one session. (ii) For the course for the First Examination, 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance during three years (including one attendance at each Practical Course in Physiology) in all subjects except Practical Pharmacy. It also entitles to the privileges of the Union Society for two sessions.

Scholarships and Prizes.—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Bucknill Scholarship, 160 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Cluff Memorial Prize, £16 biennially, Anatomy, Physiology, Pharmacology, and Chemistry; (*e*) Schafer Prize in Physiology, £18 triennially; (*f*) Sharpey Physiological Scholarship, £200, Biological Sciences; (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £10 a year; and (*h*) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. Dean: Sir George Blacker. Vice-Dean: Mr. Gwynne Williams. Secretary: Mr. G. E. Adams. Open to men and a limited number of women students. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments, as follows—first year, 70 guineas; second year, 45 guineas. This fee entitles to attendance on lectures and hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. There are over 300 beds in the hospital.

Clinical Units in Medicine and Surgery are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital. A Unit in Obstetric Medicine will be established as soon as the new Obstetric Hospital is finished.

The new buildings of the Obstetric Hospital of 60 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and the new research laboratories for the Medical School, are well under way, and these buildings should be ready for occupation in the coming winter session.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Twelve house physicians, eight house surgeons, four senior and four junior obstetric assistants (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: Resident Medical Officer, Surgical Registrar, Medical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Ophthalmic, Skin and Venereal Diseases Departments, and House Anæsthetist.

Museum of Pathological Anatomy.—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London, University College, is near the G.W.R. Perivale station.

Scholarships and Prizes.—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions, 112 guineas each, Anatomy and Physiology; (*e*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley

Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £100, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £60, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s*., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

WESTMINSTER HOSPITAL.—The hospital contains 236 beds and affords relief to upwards of 2500 in-patients and 25,000 out-patients annually. There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £70 each. Summer Session: Two Scholarships in Anatomy and Physiology, £70 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20; Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25. Inquiries may be addressed to the Dean, Dr. A. S. Woodwark.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments. This sum includes library and laboratory fees. Arrangements are made for pre-medical courses in Chemistry and Physics, which are included in these fees.

The Royal Free Hospital contains 240 beds. The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases. A new and specially equipped block contains the Obstetrical and Gynæcological Unit, which controls 68 beds. Two Research Fellows and a Research worker are engaged on work connected with the Unit. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. A new Maternity Hostel has been acquired at 434, Essex-road. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital.

Courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies. The School sports ground, consisting of 6½ acres of freehold land, is situated at Sudbury (easily reached from Euston Station), and is being developed for tennis, hockey, lacrosse, and cricket.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years, and next to be awarded in 1927. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1927, £90. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1926, £14 10*s*. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st, £20. (*k*) Helen Prideaux Prize, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £60. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1927. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s*. a year, awarded in alternate years; next award in July, 1927. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1928. (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year. (*q*) School Jubilee Bursary, *tenable for three years*, £50 a year. (*r*) Flora Murray Bursary, awarded every year to a fifth-year student, £50. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s.* and £1 1*s.* are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s.*, is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s.*, is awarded annually.

The Dean of the Medical School is Dame Louisa Aldrich-Blake, D.B.E., M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

To return to the curriculums of the Universities, there are six English provincial universities providing a full course for the medical student.

Nine degrees, two Diplomas, and one Licence are conferred—viz., the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery, and Master of Dental Surgery, the Diploma in Public Health, Diploma in Psychiatry, and the Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica, Pharmacology, Therapeutics and Pharmacy, Medical Jurisprudence, Public Health, and Pathology and Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special clinical examination in the Theory and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners. They must also produce certificates of moral character from three registered members of the medical profession. The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 24 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology and Bacteriology, *and the candidate must* submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad. The fee for the examination is £20, and the *fee for the degree is £10.*

Candidates for any of the above degrees, diplomas, or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne. *In the case of the M.D.* (essay) examination candidates must send in their essays before the 1st of April.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—University of Durham Entrance Scholarship, £25 *a year for four years*; Pears' Entrance Scholarship, £10 a year for three years (awarded every third year); Province of Durham Masonic (Entrance) Scholarship, £60; Heath Scholarship for Surgery, £200, available every second year.

The following Scholarships are tenable *for one year*, namely:—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology; Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarship for Surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £48 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £825; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for Psychological Medicine, £10. At the end of each session a Prize of Books is awarded in each of the regular classes. For further information apply to Professor R. Howden, Registrar of the College.

COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—*Clinical instruction is* given at the Royal Victoria Infirmary, containing about 550 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Students do midwifery at the Princess Mary Maternity Hospital.

Post-graduate Instruction.—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the *winter and summer* session as well as an intensive course in the summer vacation.

The Bacteriological Laboratory.—The Bacteriological Laboratory is adjacent to Armstrong College.

Students' Union Buildings have been erected and furnished at a cost of over £10,000, and are now in daily use.

Princess Mary Maternity Hospital. — The new Maternity Hospital was opened by H.R.H. Princess Mary Viscountess Lascelles in November, 1923. The hospital is thoroughly up to date, excellently equipped, and there is an annual indoor and outdoor attendance of nearly 3000 cases.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 550. The number of in-patients annually is 12,000 and out-patients' attendances 297,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1925 opens on Oct. 1st and the summer session of 1926 on April 13th. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Princess Mary Maternity Hospital, Newcastle-upon-Tyne, which contains 65 beds, with an annual indoor and outdoor attendance on 3000 cases. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye.

Post-Graduate Instruction.—For the year 1925–1926 the following post-graduate courses have been arranged:—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose and Ear; Diseases of the Skin; Venereal Diseases; Neurology. Special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation, 1926. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Biology and Organic Chemistry. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Part I., Elementary Biology and Organic Chemistry.—Part II., Anatomy and Physiology. Second Examination.—General Pathology and Bacteriology, Materia Medica, and Pharmacy. Third Examinations (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and mental hospital three months. Vaccination instruction must be taken out and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the M.Ch. A thesis of exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, Part I., £2 10*s.*; First Examination, Part II., £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £2 10*s.*; Final Examination. £10; M.D. or Ch.M., £12 10s.

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1925–26); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (e) Dental Scholarship of £37 10s., Open Competitive Examination in subjects learned during apprenticeship; (f), (g), (h), and (i) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (j) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (k) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B., Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent. The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in the fourth and fifth years (open to all students).

Post-graduate Courses.—A Lectureship in Morbid Psychology was established in 1910 in the University, and courses of lectures are given annually by specialists in the subject. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General and Queen's Hospitals are arranged annually (April to July).

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. Appointments are open to students varying from £10 to £200 a year.

BIRMINGHAM GENERAL HOSPITAL.—370 beds are in daily use, 6000 in-patients per annum. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, Septic and Infectious cases; special beds for Eye and Skin cases. About 50,000 out-patients per annum. Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electro-therapy, Extern Midwifery, and Venereal Diseases. Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 50 beds.

QUEEN'S HOSPITAL (Beds 224).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, massage, electricity, whirlpool baths, electro-cardiograph, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry; (2) Physics; (3) Biology (Zoology and Botany). The subjects of the Second Examination are (a) (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology); and (b) (3) Elementary Bacteriology, (4) Clinical Chemistry, (5) General Pathology. Candidates may present themselves in (a) or (b) separately. The subjects for the Final Examination are: (a) (1) Special Pathology and Morbid Anatomy; (2) Forensic Medicine and Toxicology; (3) Public Health; (4) Pharmacology and General Therapeutics; (b) (5) Obstetrics and Diseases of Women; (6) Surgery, Systematic, Clinical, Operative and Practical, including Ophthalmology; (7) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may present themselves in Parts (a) and (b) separately, but candidates must have completed the fifth year of medical study before taking Part (b).

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations. Candidates for the degree of Doctor of Medicine are required to present a thesis together with, if desired, published original work relative to medical science. An examination is required if the work submitted is not of special merit. If the work submitted is of special merit, but extremely specialised, a candidate may be asked to submit a reasoned report on a subject set by the examiners.

The University has recently established a Diploma in Medical Radiology and Electrology—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(*a*) Robert Gee Entrance Scholarship, annually, of £40, tenable for four years; (*b*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects; (*c*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and Materia Medica; (*d*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and (*e*) Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (*f*) University Scholarship of £50 for one year, awarded on results of Second Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; numerous prizes and medals.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has been opened.

Clinical Instruction.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital and Ladies' Charity, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1445 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.

The First Examination.—(1) Chemistry and Physics; (2) Biology. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, Biology. The candidates sit for these parts separately.

The Second Examination. — (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry.

The Third Examination.—(1) Pharmacology and Therapeutics; (2) Pathology.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts. Candidates for the Second Part must complete the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (*Branch I.*), Gynæcology (Branch II.), Ophthalmology (*Branch III.*), *Laryngology*, Otology, and Rhinology (Branch IV.).

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at this University:—Scholarships: Dreschfeld Entrance (triennial), £20; Sam Gamble Entrance for Women; two Graduate Entrance (fees up to 100 guineas); two Dauntesey Medical Junior, £50 *each*; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100. Fellowships: Leech Research, £70; Professor Tom Jones Surgical, £105; Morrison Watson in Anatomy, £150; Délépine in Preventive Medicine (biennial), £300; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology, £15; Turner Medical, £20; John Henry Agnew in Diseases of Children, £30; Dumville Surgical, £15; Knight Prize in Psychological Medicine, £50; Graduate Prizes, £5 each. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 668 patients (including 54 beds at the Central Branch). The medical side consists of five units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

The number of patients treated during the year 1924 was 10,814 in-patients and 42,348 out-patients; of the latter figure 10,058 were treated in the accident room of the Infirmary. About 9000 operations are performed annually in the operation theatres.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the City, which has now accommodation for 51 patients. The Associated Hospitals thus contain 1230 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; twelve months, 18 guineas; full period required by the Examining Bodies, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

Post-Graduate Courses.—Post-graduate Lectures open to all medical men and women are given by members of the staff and others from the last week in September until Christmas, and from the beginning of March until Whit-week. These take place at 4.15 P.M. on Tuesdays and Fridays, and are free. Information can be obtained from the Secretary of the Post-Graduate Committee, Royal Infirmary, Manchester.

The Dean of Clinical Instruction is Dr. T. H. Oliver.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and Lytham St. Anne's.—The hospital contains 190 beds and 80 in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Four Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is a new Orthopædic Department.—A special out-patients' day is held on Tuesday mornings at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 72 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Disease and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics and Gynæcology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 1st. Prospectus can be obtained from the Academic Sub-Dean.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained.

Clinical Instruction.—The Leeds General Infirmary, in connexion with this medical faculty, has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country. During 1924 11,738 in-patients and 50,777 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars may be obtained from the General Manager.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects are Anatomy and Physiology. Candidates must have completed the second year of professional study.

The Third Examination.—The subjects are Pathology, Pharmacology, Anatomy, and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study.

The Final Examination.—The subjects of the examination are:—Part I.—Forensic Medicine and Public Health; Part II.—Medicine (including Mental Diseases and Diseases of Children), Surgery, Obstetrics (including Gynæcology). Candidates for Part I. must have completed the Michaelmas Term of the fifth year of professional study; candidates for Part II. must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition to six Edgar Allen scholarships of £125 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 11 scholarships tenable in the Faculty of Medicine. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Halls, "Tapton Cliffe," "Oakholme," Clarkehouse-road; "Endcliffe House," Endcliffe Fulwood-road, and "Endcliffe House," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained of the tutor for women students. Stephenson Hall is a hall of residence for men students; particulars may be obtained from the Warden.

Clinical Instruction.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The Royal Infirmary (Secretary, Mr. J. W. Barnes), containing 502 beds, with an annual average number of over 5400 in-patients, over 16,000 out-patients, and over 19,000 casualties; the Royal Hospital (Sec., Mr. W. H. Booth), with 316 beds, and an annual number of 3600 in-patients, over 30,000 out-patients, and over 16,000 casualties; and the Jessop Hospital for Diseases of Women, with 91 beds, over 1000 in-patients, and over 2300 out-patients; also a Maternity department, with about 700 in-patients per annum and about 250 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (690 beds) and on Mental Diseases at the South Yorkshire Asylum (1740 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 818 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. Instruction is also given at the South Yorkshire Asylum (1740 beds). The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

Fees.—The Medical Composition Fee is £38 a year for each of the five years.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.) There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups—viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine, and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may be taken together or separately. Forensic Medicine and Toxicology may be taken with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e.g., Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Instruction.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in those subjects. Departments are provided and well equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological and ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: Four house surgeons, £80 each per annum; two house physicians, £80; two resident obstetric officers, one of whom is also ophthalmic house surgeon, £100 and £80; ear, nose, and throat house surgeon, £80; dental house surgeon, £80. All these appointments are made for six months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £250 per annum; casualty house surgeon, £80 per annum; two house physicians, £80 per annum; house surgeon, £80 per annum; special obstetric physician, £80 per annum; house surgeon to special departments, £80 per annum; dental house surgeon, £300 per annum. Appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £45, open to women only; Two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 6 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £14; Lady Haberfield Scholarship, value about 25 guineas; Phyllis Siepman Prize, for proficiency in Diseases of Children, value £50.

Bristol City Senior Scholarships and those offered by the counties of Gloucestershire, Somerset, Wilts, and Devon, are tenable in the University.

Some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine.

Daily Post-graduate Study.—For those who are able to devote several hours each day to hospital practice the University offers special facilities for Post-graduate work. Qualified medical practitioners may be appointed as Clinical Assistants for a period of one or more months. They may act as Assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3s. per month.

Post-graduate Clinical Work. — Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2s. All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has, inter alia, the privilege of granting Degrees in Medicine, and Diplomas in Public Health and Tuberculous Diseases. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff and is an integral part of the University College of South Wales and Monmouthshire there.

University College of South Wales and Monmouthshire, Cardiff. Welsh National School of Medicine.—This School is staffed on the Unit System, and its Courses of Instruction are open to both men and women students. Students can complete the whole of their curriculum in the School. The courses of instruction qualify for degrees in Medicine and Surgery of the University of Wales, and for the Degrees and Diplomas of other examining bodies. Hospital instruction is given at the Cardiff Royal Infirmary, at the City Lodge Hospital, and at other recognised Institutions. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at the University College, Cardiff, many of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. Medical practitioners wishing to prepare for the Diploma in Public Health or for the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the School. Prospectuses can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary. Welsh National School of Medicine.

Clinical Instruction.—CARDIFF ROYAL INFIRMARY: Founded 1837. 450 beds.—There are out-patient departments for Dermatology, Diseases of Children, and Dental Cases, and a Maternity Hospital.—SWANSEA GENERAL AND EYE HOSPITAL: Hospital, 262 beds. Departments: Pathological Laboratory; Venereal Diseases Department; Ophthalmic; Ear, Nose and Throat; Women; X Ray and Massage. Convalescent Home, 26 beds.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

1. *Regulations applying to all candidates who passed the required Preliminary Examination in General Education before Jan. 1st*, 1923.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate must give notice in writing to Mr. F. G. Hallett, O.B.E., Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C.1, 14 clear days before the day of the examination, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, and Elementary Biology. A candidate may take this examination in two parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, and in Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine in any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects.

The fees for admission to the *First Examination* are as follows: For the whole examination, First Admission, £10 10s.; re-examination in Chemistry, £3 3s.; re-examination in Physics, £2 2s.; re-examination in Biology, £3 3s. *Second Conjoint*: This examination is in two parts—viz.: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacology. A candidate must have attended at a recognised medical school, lectures on Anatomy, Physiology, and a course of Practical Physiology and Histology, and have dissected for twelve months during the ordinary sessions. He must also attend three months' lectures or demonstrations in Practical Pharmacology and receive instruction in Practical

Pharmacy. Part II. may be passed at the same time as Part I., or before or after that part. The study of Anatomy and Physiology before passing in two of the three subjects of the first examination is not recognised. If rejected, a candidate before being admitted to re-examination must continue his studies at a recognised medical school for not less than three months.

Second Examination: £10 10*s.*; re-examination in Part I., £6 6*s.*; re-examination in Part II., £3 3*s.*

The subjects of the *Third* or *Final Examination* are: Part I., Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health. Part II., Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III., Midwifery and Diseases Peculiar to Women. Candidates may present themselves for Parts I., II., and III. of the examination separately or together at the expiration of not less than two years (24 months) from the date of passing the Second Examination on production of the certificates of study required for the respective parts, provided that the examination is not completed before the expiration of five years from the date of passing the Preliminary Examination.

The fees for admission to the *Third or Final Examination* are as follows: *Third Examination:* £21; re-examination in Part I., Medicine, £6 6*s.*; Part II., Surgery, £6 6*s.*; Part III., Midwifery and Diseases of Women, £4 4*s.* Members of English, Scotch, or Irish Universities £5 5*s.* for first admission to the examination and £36 15*s.* for the diplomas.

A candidate referred on the *Third or Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

2. *Regulations applicable to candidates who passed the required Preliminary Examination in General Education on or after Jan. 1st, 1923.*

Students are required to pass a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board; a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be *allowed to* pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed. The examination is partly written, partly oral and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure. The fee for the examination is £3 3*s.*, for re-examination in Chemistry £2 2*s.*, and for re-examination in Physics £1 1*s.*

There are two Professional examinations called the *First* and *Final Examinations.* The courses of study for these examinations must not be commenced until the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Bio-Chemistry. Section II. Pharmacology, Practical Pharmacy and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Bio-Chemistry and Bio-Physics during five terms, courses of instruction in Pharmacology, Practical Pharmacy and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s.*, for re-examination after rejection in Section I. £6 6*s.*, for re-examination, after rejection in either part of Section I. £3 3*s.*, for re-examination after rejection in Section II. £3 3*s.* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. (*a*) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology. (*b*) Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s.*; for admission to Section II., Part I., £10 10*s.*; Part II., £10 10*s.*; Part III., £6 6*s.*; and the re-examination fees are respectively £3 3*s.*, £6 6*s.*, £6 6*s.*, and £4 4*s.*

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second

Examinations of the Examining Board under the old Regulations, or of the First Examination and Section I. of the Final Examination under the new Regulations may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Laryngology and Otology. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them. The candidate must either have passed the examinations for the licence of the College, or else be a registered medical practitioner who has obtained the degree of Doctor or Bachelor of Medicine at a University recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the *Registrar* at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 6 guineas, which is reckoned as part of the fee for admission in the case of success.

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The *Royal College of Surgeons* of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce and include the examination of patients and the performance of operations on the dead body. The *First Examination* will in future years be held in June and December and the Second Examination in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each re-admission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, of the equivalent examinations in his University, on the production of certificates of attendance upon prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly. Part I. Chemistry, Chemical Physics; Practical Chemistry; Biology, Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. Part I. Clinical Surgery: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Clinical Medicine: Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. *Part III. includes* Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments.

The course of study for the *Final examination* includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of two winter and two summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over five years, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the *Society*. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before sitting for any part of the Final examination.

Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses four hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, 58 beds, London, N.W. 1; Tilbury Hospital, Tilbury Docks, Essex, 52 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds, and the Angas Home, Cudham, 30 beds. Total, 520 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals.

In conjunction with the Fellowship of Medicine arrangements have been made for a course of operative surgery. Secretary: Sir P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—This hospital has 210 beds, all of which are constantly in use. 2531 in-patients and 40,029 out-patients, whose attendances numbered 108,041, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology. The fees for hospital practice, including lectures, are £4 4*s.* for one month, £9 9*s.* for three months, or £22 1*s.* for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Sir Henry Simson, at the Hospital. Secretary of the Post-graduate College Mr. C. Cole, and of the Hospital Mr. H. A. Madge.

ROYAL NORTHERN GROUP OF HOSPITALS.—The Royal Northern Hospital, Holloway, London, N. 7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Hospital of Recovery, Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 394. The Royal Northern Hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the honorary staff there are six anæsthetists, three pathologists, resident medical officer, resident house physician, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the two operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. Special departments include the following: Fracture, genito-urinary and neurological, physico-therapeutic, pathological (under a director of clinical pathology), tuberculosis, and venereal diseases. Patients are removed to the Hospital of Recovery by ambulance a few days after operation. Medical practitioners are cordially invited to see the general and special practice of the Hospital. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Special Departments.—A new maternity department has been opened, and the light department has been re-equipped.

Post-Graduate Facilities.—In association with the Fellowship of Medicine, two-week "refresher" courses have been arranged for March, July, and November. These will include teaching in general medicine and surgery, and special lectures and demonstrations in special subjects at the Royal Northern and Royal Chest Hospitals.

Further particulars can be obtained from the Secretary of the Medical Committee of the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 200 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are five resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Dr. C. S. Shanks, Secretary to the Medical Committee, 24, Weymouth-street, W. 1; or from Dr. A. J. Whiting, Dean of the College, 19A, Cavendish-square, W. 1.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 135 beds. The in-patients in 1924 were 1002, and the out-patients and casualties numbered 12,006 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Monday, 1.30 P.M., Tuesday, 2.30 P.M., Wednesday, 9 A.M. and 1 P.M., Thursday, 8 A.M., Friday, 10 A.M. and 3 P.M., and Saturday, 9 A.M. New Out-patient Departments for special diseases have been opened: Neurology, Diseases of the Stomach and Disorders of Digestion, Diseases of Women, Genito-Urinary Diseases, Diseases of the Rectum, and Dermatology.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—The Hampstead General Hospital (Haverstock-hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 100 free, 8 isolation and observation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients' Department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital. Post-graduate work is in connexion with the Fellowship of Medicine.

SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.; Out-patient Department: 88-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 113 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, Urological, X ray and Electrical, Pathological, Physio-Therapeutic, and Dental Departments. The hospital is a centre for the treatment of venereal diseases under the Public Health (Venereal Diseases) Regulations, 1916. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1924 was 1618 At the Out-patient Department in Newington Causeway 9134 new cases were treated during the past year, the total number of out-patient attendances amounting to 36,193. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Two resident students act as clinical clerks in the surgical wards. Secretary: Miss M. E. Ridler.

French Hospital and Dispensary, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. J. Knecht.

Italian Hospital, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

German Hospital, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for others in cases of emergency and accident. It has 154 beds and a sanatorium with 10 beds: also a Convalescent Home at Hitchin.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuro-Pathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist. The hospital has been recognised by the Conjoint Board of England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary.

Hospital for Epilepsy and Paralysis, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh. The out-patient department is open every week-day except Saturday at 2 P.M.

West End Hospital for Nervous Diseases.—Out-patient Department, Welbeck-street, W.; In-patient Department, Gloucester Gate, Regent's Park, N.W.; 76 beds, over 48,500 out-patient attendances. Complete reconstruction has recently been effected and the hospital offers all facilities for instruction in Neurological subjects. A series of clinical demonstrations, apart from the general practice of the hospital, is held regularly each session, and the hospital is coöperating with the Fellowship of Medicine in the programme of special post-graduate teaching organised by the Association. The Savill Memorial Prize (value £15) and Medal are offered biennially for competition among post-graduate students who have attended at the hospital. For further particulars apply to C. C. Worster-Drought, M.D. (Dean), or to J. P. Wetenhall, B.A., Secretary, 73, Welbeck-street, W. 1.

Bethlem Royal Hospital, St. George's-road, S.E. This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive clinical instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee. A Department for Nervous Diseases has been instituted in a building quite apart from the main hospital. Neurological and early mental cases are dealt with. A Course of Lectures and Practical Instruction for the Diploma in Psychological Medicine granted by the various Universities, will commence in the middle of September. For particulars apply to the Physician Superintendent.

Hospital for Consumption and Diseases of the Chest, Brompton.—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital: terms £1 1*s.* for one month; three months, £2 2*s.* Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students. During the month previous to each conjoint examination the teaching will be as far as possible for students about to enter for the final examination. Dean of the Medical School: Dr. L. S. Burrell, from whom all particulars can be obtained.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E. 2.—During the past year 1186 in-patients have been treated in the wards. The out-patients treated during 1924 numbered 8331. Special Departments: Surgical, Laryngological, Radiological, Pathological, Electro-Cardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The In-patient staff visit generally in the afternoon; Out-patients at 2 P.M. The Post-Graduate Association is open to graduates on payment of fee of 1 guinea per annum, which entitles them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, particulars of fees for which can be obtained from the Dean. A club room is also provided. Application for prospectus, &c., should be made to the Dean. Graduates desiring Assistantships in any department should apply to the head of the Department. Physicians to In-patients: E. H. Colbeck, Clive Riviere, A. G. Levy, A. J. Scott-Pinchin, F. G. Chandler, Sir Percy Bassett-Smith; Surgeon: W. H. C. Romanis; Laryngologist: W. G. Howarth; Physicians to Out-patients: J. B. Alexander, J. B. Christopherson, V. S. Hodson; Electro-Cardiographic Department: A. J. Scott-Pinchin; Radiologists: B. J. Leggett, J. V. Sparks; Pathologist: S. R

Gloyne; Assistant Pathologist: D. S. Page; Dental Surgeon: W. Elder. Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney). Tuberculosis Officers: H. T. Howell and F. W. Hamilton. Other information from the Secretary.

ROYAL CHEST HOSPITAL (for all affections of the heart and lungs), City-road, E.C. (85 beds). Branch of the Royal Northern Hospital, Holloway.—This hospital provides accommodation for 85 in-patients. Expenditure for 1924, *£14,508 10s. 8d.*; income, £14,168 7s. *11d.* The attendance of out-patients 80,000 annually. Secretary: Mr. G. G. Panter.

MOUNT VERNON HOSPITAL (INCORPORATED) FOR TUBERCULOSIS AND DISEASES OF THE LUNGS AND HEART, Northwood; CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.—The *hospital contains* 150 beds, Medical and Surgical; 50 beds reserved for children requiring surgical aid. Number of in-patients, 476; out-patients, 13,880. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. New departments for artificial light treatment have been opened both in the hospital and the *out-patient* department. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL (formerly QUEEN CHARLOTTE'S LYING-IN HOSPITAL) AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital receives about 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative *midwifery*, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable *instruction in the Antenatal* Department, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially trained. A Residential College provides accommodation for five men and two women at a time, students and qualified practitioners, and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. For further particulars application should be made to Mr. Arthur Watts, Secretary.

HOSPITAL FOR WOMEN, Soho-square, W.—The teaching in connexion with the above hospital has been greatly extended, and is available for Post-Graduates only, in limited numbers. Every facility is afforded them, by the teaching staff, of obtaining experience in diagnosis and treatment of Gynæcological diseases. The hospital contains 68 beds, and the out-patient attendances are over 14,000 per annum. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can *also* be gained in the treatment of malignant disease by means of radium. Incorporated is the London School of *Gynæcology*, comprising attendance in Out-patient department, operating theatre, clinical lectures, and X ray treatment. *For further particulars* apply to the Secretary.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. The *fees, payable* in advance, are £3 3s. for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—The hospital maintains 180 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All *particulars may* be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be *obtained on applying to* Mr. W. M. Wilcox, the Secretary.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.1 (contains 214 beds).—The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months *of the fifth year may be spent in clinical* work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the *London School* of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to eight medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, 2 guineas; *three months*, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1s. for one month's attendance. *Pathological Clerkships.—Facilities are afforded* for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3s.; for two months, £5 5s.; for three months, £6 6s. A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These *appointments are open to students* of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application *to the Dean or* Secretary at the hospital. The medical school is a constituent part of the London Post-Graduate Association. *Secretary*: Mr. James McKay.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—This hospital contains 70 cots and a very extensive Out-*patient* Department. Clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, may be appointed quarterly for a period of three months; there is no salary attached to these posts; but, on the other hand, no fees *are charged*.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—The hospital contains 130 beds and has a large out-patient department (over 1400 weekly); the home at Broadstairs has *50* beds. *Out-patients* are seen as under:—Diseases of the Eye: Thursday, 2 P.M. Diseases of the Skin: Monday, 1.30 P.M. Whooping-cough Cases: Friday, 2 P.M. Dental Cases: Tuesday, 1.30 P.M. Medical and Surgical Cases: Mornings at 9.30 and 11.30. *Accidents and* urgent cases are admitted at any time. Secretary: Mr. D. St. John Bamford.

A Private Nursing Home for Children is now open at 29, Tite-street, in connexion with and adjacent to the hospital. Terms: £1 1s. per day or £5 5s. per week. Application for admission should be made to the Secretary. Patients must be under the care of a consultant of one of the hospitals of London, and the question of payment for his fees is a matter of arrangement between him and the child's parents.

Queen's Hospital for Children (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E. 2. (Telephone 305 and 534 Clissold.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch, "Little Folks" Home, Bexhill.—During the past year 1627 in-patients and 38,779 out-patients (attendance 145,097) were received. The surgeons attend on Monday, Wednesday, and Friday at 9 A.M., and on Thursday at 1.30 P.M.; the physicians daily at 1.45 P.M., except Saturday, and also Wednesday and Friday, 9.30 A.M., as well as 1.45 P.M. Whooping-cough Physician: Saturday, 9.30 A.M. Skin Physician: Friday, 1.30 P.M. Ear, Nose, and Throat Surgeons: Monday, Tuesday, and Thursday, 9.30 A.M. Eye Surgeon: Wednesday, 1.30 P.M. X ray department open every day. Radiologist attends Monday, Tuesday, Wednesday, and Friday, 2 P.M. Dental department every morning, 9.30, except Saturday; also on Tuesday and Friday, 2 P.M. Massage department daily, morning and afternoon (except Saturday afternoon). The practice of the hospital is open to students by arrangement with the medical staff. Post-Graduate instruction in Children's Diseases, Lectures and Demonstrations at times that will be notified by the Fellowship of Medicine. Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

Belgrave Hospital for Children, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

Alexandra Hospital for Children with Hip Disease (late of Queen-square, W.C.), Kettlewell Home, Swanley, Kent (in connexion with St. Bartholomew's Hospital).—At this hospital cases of hip-disease, spinal caries, and tuberculous diseases of other bones and joints are treated. Students who have obtained a recommendation from their teachers can attend to see the practice. In-patients, Swanley, Kent; Out-patients, St. Bartholomew's Hospital; Fridays, 1.30 P.M. Apply for particulars to the Dean of the Medical College, St. Bartholomew's Hospital, E.C. 1.

Royal London Ophthalmic Hospital (Moorfields, 1804–1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. Last year there were 2458 in-patients, the out-patients were 49,932, of whom 43,435 were new out-patients, and the attendances were 116,687. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3s.; perpetual, £5 5s. Special courses of instruction, which extend over a period of five months, are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4s.) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. A special course is also held in the preliminary subjects (Anatomy, Physiology, and Optics) for the various degrees in Ophthalmology. The fee for this course is 12 guineas. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. A. J. M. Tarrant, Secretary.

Royal Westminster Ophthalmic Hospital, King William-street (next door to Charing Cross Hospital), Strand, W.C. 2.—The hospital contains 42 beds. Out-patients, who number over 14,000 annually, are seen daily at 1 P.M., and operations are performed in the theatre at 3 P.M. The practice of the hospital is open to both men and women practitioners and students. Clinical evenings, at which interesting cases are shown and discussed, are held twice each term at 8 P.M. on the second Tuesday of the month. In addition to the ordinary clinical instruction, a systematic course of Lectures and Practical Classes commences in October and May. Lectures in this course are given daily (except on Saturday) at 4.30 P.M., including all subjects required by candidates for the D.O.M.S., R.C.P. & S. Eng., Part II., and practical instruction is given in Operative Surgery and Ophthalmic Pathology and Bacteriology. A corneal microscope has been purchased and instruction in the Microscopy of the Living Eye can now be obtained. Fees: One month, £1 1s.; three months, £2 2s.; six months, £3 3s.; perpetual, £5 5s.; composition fee for perpetual ticket and attendance at classes (except Operative Surgery and Pathology, for which fee in each case is £2 2s. per course), £10 10s. Students of the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant, and senior or junior clinical assistant. Full details can be obtained on application to the Dean.

Royal Eye Hospital, St. George's-circus, Southwark, S.E. 1.—There are 40 beds and 2 cots. In 1924 there were 51,206 attendances in the Out-patient Department, the new patients being 22,218. The daily average of attendances was 173 patients. In-patient admissions numbered 755. Clinical instruction is given to students and post-graduates daily at 2.30 P.M., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparation for examinations in Ophthalmology. Apparatus has been installed for the Microscopy of the Living Eye. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. Dean: Mr. A. D. Griffith.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—This hospital has 40 beds and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 2 and 4 o'clock. This school is recognised as a teaching institution by the Universities of London and Oxford, and the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The school has also undertaken to receive a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. Secretary: H. R. S. Druce.

Western Ophthalmic Hospital, Marylebone-road, N.W.—18 beds. Out-patient attendances, 30,024. Both In-patient and Out-patient Departments of this Hospital are open to medical graduates. Fees £1 1s. per three months. Honorary Secretary: H. W. Burleigh.

National Hospital for Diseases of the Heart, Westmoreland-street, London, W. (founded 1857).—The practice of the hospital, both in the wards and out-patient department, is open daily to post-graduates and others, and will be found valuable by those seeking the higher qualifications—e.g., M.D., M.R.C.P., &c. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the Cardio-Vascular system, and facilities exist for those requiring practical instruction in Electro-cardiography, X Rays, and other graphic methods. Clinical Assistants in the Out-patient Department are appointed from time to time. For further particulars apply to the Dean of the Medical School (Dr. Parsons-Smith), or to the Secretary, at the hospital.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W. (with which is amalgamated the London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. There is an annual out-patient attendance of over 60,000. Minor operations are performed on Tuesdays, Wednesdays, and Thursdays, at 9.30 A.M. The hospital has been partially closed for some time owing to rebuilding operations. The new wards and in-patient operating theatres are expected to re-open in October. When completed the hospital will contain some 80 beds. Practitioners and medical students are admitted to the practice of the hospital at a fee of £5 5*s*. for three months, £7 7*s*. for six months, or £10 10*s*. for perpetual studentship. From amongst the students junior clinical assistants are appointed periodically. For terms and further information apply to the Dean, Mr. Gilbert Chubb.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.—The practice of the hospital is largely consultative. The hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinique. An Intensive Course of Lectures with Operative Surgery Class is given twice yearly—in May and October. Consultations on interesting cases take place on the second Wednesday in each month at 4 P.M. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening Clinics. Full syllabus can be obtained on application to the Dean.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily (Saturdays excepted) at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 10 A.M. Fee for one month's attendance at the hospital £3 3*s*., and for three months £5 5*s*. Clinical Assistants are appointed as vacancies occur, and have responsible duties. Applications should be made to the Secretary, L. L. Phillips.

ROYAL EAR HOSPITAL.—This hospital is now the Ear, Nose and Throat Department of University College Hospital. All out-patient clinics are now held at University College Hospital in Gower-street, but ward visits and operations by the staff take place each afternoon (except Fridays and Saturdays) at Dean-street.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C. 1. (Founded 1835.)—The hospital contains for men and women 54 beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Two fortnightly courses held during year in coöperation with the Fellowship of Medicine and Post-Graduate Medical Association. Average out-patient attendances, 4000 per year. Average in-patients, 675 per year.

ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES, *Henrietta-street, Covent Garden.* Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, excepting that the only out-patient clinic open to medical women is that held at 2 P.M. Fridays for women and children, and to the operations in the theatre on Mondays at 2.30 P.M., and Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 30; average out-patients seen daily, 80. Post-graduate Courses of Lectures are arranged through the Fellowship of Medicine from time to time.

LONDON SCHOOL OF DERMATOLOGY, ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C. 2. In-patient Department (34 beds) at 262, Uxbridge-road, W. 12.—Out-patient Clinics are held daily at 2 and 6 P.M. (Saturdays 2 P.M. only), when demonstrations are given on the cases presenting themselves. The Chesterfield Lectures, constituting a systematic course in dermatology, are given on Tuesdays and Thursdays at 5 P.M., from October to March, by the hon. medical staff of St. John's Hospital and the physicians in charge of the Dermatological Departments of the London Teaching Hospitals. The lectures are free to those attending the practice of the hospital and to registered medical students. At the end of the course an examination is held for the Chesterfield Medal in Dermatology and is open to those who have attended three-quarters of the lectures. The Electrical Department is open daily from 2 to 4 P.M., except on Thursdays and Saturdays. Laboratory Courses in the Pathology and Bacteriology of the Skin can be arranged. For further particulars and fees apply to the Dean. Dr. A. C. Roxburgh.

LONDON LOCK HOSPITAL AND HOME (Founded 1746).—In the Institution at Harrow-road, W. 9, there are 202 beds, and 664 in-patients and 10,958 (attendances) out-patients were dealt with in 1924. In the Male Department and Out-patient Department in Dean-street, Soho, W., there are 40 beds, which during 1924 accommodated 822 patients. 90,881 out-patient attendances were made in the various departments. 8064 injections of substitutes for salvarsan, &c., were made in 1924. Male patients are seen at 91, Dean-street on Mondays and Tuesdays from 1 to 2 P.M., and from 6 to 8 P.M.; on Wednesdays from 6 to 8 P.M.; on Wednesdays at 1 P.M. (female patients); on Thursdays, 1 P.M. (male out-patients), 5 P.M. (female patients); on Fridays from 5 to 7 P.M. (male patients); and on Saturdays from 2 to 4 P.M. (males). Pathological Department, daily at 6.30 P.M. Intravenous injections are given at every clinic. Female clinics are held at 283, Harrow-road, Paddington, on Mondays at 10 A.M., Tuesdays, Wednesdays, and Thursdays at 2 P.M. to 3 P.M., and Saturdays at 2 P.M. The new female out-patient department is open all day long from 9 A.M. to 8 P.M. Irrigations for males are given daily 8 A.M. to 10 P.M. For females Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays at 11 A.M. to 1 P.M., at 91, Dean-street. The Hospital is linked up with the Fellowship of Medicine, and special courses of lectures are held in February, May, and November each year. Application for tickets should be made direct to the Secretary. Only a limited number of practitioners and students are permitted to attend the Female Lock Hospital, and application should first be made to Major Corbett (Dean) at the Male Lock Hospital; or to the Secretary, Hy. J. Eason, at the Chief Offices, 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is omitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located. Most of the larger general hospitals of the kingdom have already been noticed in connexion with the Universities.

BATH ROYAL UNITED HOSPITAL, Bath.—This hospital contains 206 beds, 72 of which are situated in Combe Park, Bath, and are for *paying patients* only, and possesses X ray, Massage, Bacteriological Departments, a new Pathological Laboratory, and a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), from 5 to 6.30 P.M., and Ear, Throat, and Nose Clinics on Thursdays, at 4 P.M.

BEDFORD COUNTY HOSPITAL, Bedford.—This hospital has 109 beds, including 15 beds in the paying wards, X ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, nr. Woburn Sands. The hospital is approved by the University of London for the purposes of the M.D. and M.S. Examinations. Secretary: Mr. Beauchamp Wadmore.

BRADFORD ROYAL INFIRMARY, Bradford. — This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynæcological work, and affords excellent facilities for either students or post-graduates. There are special clinics for Orthopædic cases. Plans for a new hospital of 300 beds have been adopted, and building operations will be commenced as soon as funds will allow.

ROYAL SUSSEX COUNTY HOSPITAL, Brighton (225 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Gynæcological, X ray, and Orthopædic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

KENT AND CANTERBURY GENERAL HOSPITAL, Canterbury.—The hospital contains 116 beds. Pupils of the staff are admitted to the practice of the hospital. Operations four days of the week. There is an Ophthalmic Department with two wards for in-patients, a Venereal Clinic, an Orthopædic Department, &c. Secretary, Mr. F. P. Carroll.

COVENTRY AND WARWICKSHIRE HOSPITAL, Coventry (established 1840).—This hospital contains 241 beds. Special clinics are held for diseases of the Eyes, Ears, Nose and Throat; Gynæcology; X ray and Electrical Treatment. There are also V.D. Clinics. A Pathological Department has recently been started. Clinical students are received, and there are paying wards. Secretary: Miss R. Hooper.

DERBYSHIRE ROYAL INFIRMARY, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynæcological cases. There are four resident house surgeons, a resident house physician, and an assistant house surgeon and casualty officer. There are also well-equipped orthopædic, X ray, electrical, and venereal diseases departments. Registered medical students are admitted to witness the medical and surgical practice on payment of such fees as the Board may determine.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 225 beds (including special children's wards) and has a good library, museum, post-mortem room, and pathological laboratory. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897 and the "Victory" wing for the treatment of discharged disabled soldiers and sailors completed and opened in 1922. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. This department is now enlarged to meet the ever-increasing work, and now forms one of the most important sections of the hospital. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1924, 3452. A ward is set aside for newly-born babies suffering from infectious eye diseases. Mothers are accommodated with their babies.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: G. Hurford. In-patients, 1986; out-patients, 10,600. An electrical and massage department has been established and venereal clinic opened. Also ear, nose and throat department, X ray department, dental department, and pathological laboratory.

NORTH STAFFORDSHIRE ROYAL INFIRMARY, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 304 patients, including Children's wards, a Bacteriological and Pathological department, and a department for the treatment of Diseases of the Eye, X Ray and Electrical department, a department for the treatment of Diseases of the Ear, Nose, and Throat, an Orthopædic department, and Venereal Diseases clinics; so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient department, costing £12,000, a new Children's ward of 30 beds, a new Pathological department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. An Electrocardiograph has been recently installed. H.M. King George V. laid the foundation-stone of a new Ward block on June 5th. Secretary and House Governor: Mr. W. Stevenson.

HULL ROYAL INFIRMARY, Hull.—This hospital contains 207 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements, including an up-to-date pathological department recently added. A branch convalescent home at Withernsea, with accommodation for 30 patients, is a special feature of the charity.

LEICESTER ROYAL INFIRMARY, Leicester.—Instruction in the Infirmary for medical students is duly recognised by the various examining bodies. At the General Infirmary there are 338 beds, and at the Children's Hospital in connexion 70; venereal diseases, 17; total 420 beds. A reconstruction scheme has been carried out, and £250,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, two new wings, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Pathological Laboratories and post-mortem rooms were rebuilt at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms, and now provides for 100 nurses and staff. The 150th anniversary of the Institution has recently passed and a sum of £100,000 was raised in commemoration. Funds are being raised for the foundation of a City University, and a splendid site was presented by the late Mr. T. Fielding Johnson, J.P., an ex-chairman of the Royal Infirmary. There are ten resident salaried medical officers at the Infirmary —viz., four house surgeons, two house physicians, two anæsthetists, and two dressers. Most of the posts are filled half-yearly and afford exceptional opportunities for post-graduate experience and senior students. Dressers are given an honorarium. Students are encouraged to make full use of the facilities which exist to gain clinical knowledge in the wards. The hon. medical and surgical staff are willing to afford instruction in a variety of conditions which an active and well-equipped general hospital in a large commercial centre is called upon to treat. A post-graduate course of lectures is arranged annually by the Leicester Medical Association and also clinical classes are held for graduates preparing for the M.D. and M.R.C.P. New accommodation for resident medical officers has been erected. Chairman of the Board: Mr. J. G. Pickard. Deputy Chairman of the Board: Lieut.-Col. C. F. Oliver, D.L., V.D. House Governor and Secretary: Mr. Harry Johnson, from whom information as to prospective vacancies on the Resident Staff may be obtained.

A private hospital has been presented to the City by Mr. Thomas Fielding Johnson, J.P., son of the donor of the University site. This magnificent gift comprises three large dwelling-houses on an admirable site, which have been reconstructed and re-equipped as a private hospital for the reception of paying patients.

NORTHAMPTON GENERAL HOSPITAL, Northampton. Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 100. Non-resident pupils receive and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s. Pupils can be received at any time. There is an up-to-date Pathological Laboratory; also X Ray and Therapeutic Department and V.D. Clinic.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This hospital has at present 300 beds. There is a convalescent home at Cromer. Students are admitted to the practice of the hospital for a fee of £5 5s. for six months. Secretary: Mr. Frank Inch.

NOTTINGHAM GENERAL HOSPITAL.—There are at this hospital 317 beds available for medical and surgical patients, and 45 beds are in the detached branch known as "The Cedars" Convalescent Hospital, Woodthorpe. The Medical and Surgical Staffs consist of 2 Honorary Consulting Physicians, 3 Honorary Consulting Surgeons, 1 Honorary Consulting Physician in Venereal Diseases, 3 Honorary Physicians, 4 Honorary Surgeons, 2 Honorary Assistant Physicians, 2 Honorary Assistant Surgeons, 2 Honorary Aural Surgeons, 1 Honorary Dermatologist, 2 Honorary Anæsthetists, 1 Honorary Surgeon Dentist, 1 Honorary Medical Officer in Charge of X ray and Electro-therapeutic department, and 1 Pathologist. The Resident Medical Staff consists of 2 House Physicians, 4 House Surgeons, 1 Aural House Surgeon, and 1 Casualty Officer. The special departments are the Ear, Nose and Throat, Skin, Dental, Massage and Exercise, X ray, Orthopædic, Electro-therapeutic. House Governor and Secretary: Mr. P. M. MacColl.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—This hospital contains 195 beds (14 of which are for Venereal Diseases in a separate building). There are three Pathological Laboratories, special Departments for X Ray, including Deep Therapy, Ultra-violet Rays, and Electro-therapeutics, and a large Orthopædic Department. Pensioners are received as in-patients. The hospital is a centre for the treatment of Tropical Diseases. A building with 25 additional beds is in course of erection.

ROYAL HOSPITAL, Portsmouth (founded 1847).—The number of beds is 160. There are X ray and Massage Departments. The hospital is a preparatory school of Medicine and Surgery; the attendance of pupils is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

ROYAL BERKSHIRE HOSPITAL, Reading.—This hospital, which contains 220 beds, was enlarged in 1912, and includes an Out patient Department, a Casualty Department, an X ray Department, Electro-therapeutic and Massage Department, a V.D. clinic, a Laboratory, an Eye Theatre, Eye Wards, and Motor and Horse ambulances. The hospital is approved by the General Nursing Council as a Training School for Nurses. Post-Graduate Lectures are given.

SALISBURY GENERAL INFIRMARY, Salisbury.—This hospital contains 145 beds. The daily average number of in-patients is 127; number of new out-patients, 4266; number of out-patient attendances, 20,116, including 8577 casualties, 1221 medical and surgical out-patients, 738 ear, nose and throat cases, 840 ophthalmic cases, 723 dental cases, 3484 venereal cases, 754 X ray cases, and 6089 massage and electrical cases. Special features: Maternity and antenatal, ophthalmic and private wards; maternity and child welfare clinic. House Governor and Secretary: John S. Birbeck.

ROYAL SALOP INFIRMARY, Shrewsbury.—This hospital has 180 beds. In-patients, 1575; out-patients, 1000; out-patients' attendances, 16,410; accidents and casualties, 2524; dental cases, 380. A site has been purchased adjoining the present Infirmary structure, and it is proposed to erect an annexe for women and children thereon. Secretary: Mr. Alfred Suglen.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.—This hospital contains 130 beds. In-patients 3006; out-patients, 13,100. Secretary: Mr. T. A. Fisher Hall.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford (established 1766).—This hospital has 87 beds. In-patients, 1139; out-patients, 3190. Secretary: Lieut. A. E. Collins.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—This hospital has 158 civilian beds. Secretary: Mr. Herbert Maslen.

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL, Wolverhampton.—There are 210 beds. Special departments for Children, Infectious cases, Gynæcology, Ear, Throat, and Nose Diseases, Electrotherapeutic and X ray, Venereal Disease, Pathological Laboratory, Dentistry, and Electro-cardiographic Installation. There is an excellent library. The resident officers are a resident surgical officer, resident medical officer, and two house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee. In 1924, 3567 in-patients and 28,290 out-patients were treated; 3721 operations were performed in the theatres.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds. Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 1009. New X ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII., and fire-escape staircases recently erected. In-patients, 1360; out-patients, 4397. Secretary: Mr. E. J. Holland.

YORK COUNTY HOSPITAL, York.—This hospital contains 180 beds. There are balconies for outdoor treatment, two installations of X ray apparatus, electro-therapeutic and massage department, and clinical laboratory. A Venereal Diseases Clinic is held.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (recognised by the UNIVERSITY OF LONDON).—The subjects of the qualifying examination of the Pharmaceutical Society are:—Part 1: (*a*) Chemistry; (*b*) Physics; (*c*) Botany. Part 2: (*a*) Materia Medica; (*b*) Pharmacy, including Posology and the Translation and Dispensing of Prescriptions; (*c*) the law relating to the keeping, selling, and dispensing of poisons and poisonous substances. Fee, 12 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry, physics, practical chemistry, and materia medica. Fee, 3 guineas. Courses of instruction are given for Part 2 and for the Major Examination (but not for Part 1). An Intercollegiate, two years' course for the Final examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates in Science may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories. Application for admission to the school, or for further information, may be made to the Dean, Prof. Greenish, 17, Bloomsbury-square, London, W.C. 1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course of instruction in Clinical and Practical Midwifery and have personally conducted 12 cases of labour.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £34 13*s*., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £9 9*s*.; for the Second Division (Anatomy and Physiology), £7 7*s*.; for the Third Division (Pathology and Materia Medica and Therapeutics), £6 6*s*.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £11 11*s*.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £21, and the fee to be paid for the degree of Ch.M. is £21.

Post-Graduate Instruction.—Courses of instruction are given for the Degrees of B.Sc. and D.Sc. in Public Health and for the University *Diplomas* in Public Health, Tropical Medicine and Hygiene, and Psychiatry. These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University. The University also takes part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been accepted by the Senatus.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 14th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £170, payment of which is distributed over the period of study.

Post-graduate Courses are conducted in conjunction with the University.

Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Post-graduate Courses of Lectures are held during the year. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A post-graduate course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences on Oct. 13th, 1925. The class meets at 5 P.M. Tuesdays and Fridays, and the instruction, which is practical, is supplemented by lantern demonstrations. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

UNIVERSITY OF GLASGOW.
